"Well," Dr. Dana responded with a smile, "an extra hour or two of rest might mean opportunity to drink, gamble, go to cheap shows, overeat, quarrel with one's wife, or any number of other profitless and joyless occupations. That same time spent in really playing baseball, golf, tennis, or in music or reading would yield greater return, surely, to body and mind. I believe in recreation as preferable to amusement. In recreation, *you* do something. In amusement *you see* it done."

Early Habits Count

Dr. Dana dilated considerably upon the matter of reading. He regretted that such large numbers of people fail to form the habit when young and thus deprive themselves of this incomparable solace when years have crept upon them.

"I know a young man of twenty-four," he said by way of illustration, "who is in business with his father and whose one-sided recreational interest centers about the prize fighting ring and similar places, to whom I recently suggested that he take up H. G. Wells 'Outlines of History' and read it."

"Who is Wells?" was his reply.

"Yes, I know this sounds incredible, coming from a person with cultural opportunities; but it is true nevertheless."

Dr. Dana emphasized his belief that the capacity for intelligent recreation should be evoked in early youth, and a sense of its profound importance built up at the same time.

He mentioned two classes of persons from whom his patients are largely drawn, who are victims of an educational method that has failed to impress upon them a vital sense of the value of leisure time.

"Business men who have concentrated on making money, and women with nothing to do, are seemingly at opposite poles," said Dr. Dana. "Yet actually they arrive by diverse paths at the same goal of nervous upset."

"Let us take the business man first. He has devoted every thought and impulse over a long period of years

to problems of financial advancement. I am speaking now not merely of eager money makers, but also of many who simply are conscientiously trying to support their families and secure a competence for their old age. Doubtless the business man has thought that 'some day' he would relax, and go in for the joys of leisure which he is temporarily passing by. But alas! there are inexorable psychological laws whereby capacities which are unexercised gradually lose their flexibility, and finally atrophy, just as there are physical laws which make the same thing true of muscles. Interest in the cultural phases of life—in art, literature, music, social problems, and politics—disappears in about ten years; in twenty, it is almost beyond recall.

"The business man, then, arrives at a moment when his children have grown up and gone their own way in the world; he has made all the money he wants; he is 'fed up' with his unintermittent pursuit of riches; and he is conscious of vague, unformed longings for other interests. But he has developed a one-track mind; and, despite himself, he cannot pull out of the groove which long usage has worn so deep. This man's tragedy is that he did not have the proper warning, and the proper training, in his youth; if he had, he might have developed a few parallel tracks throughout the years, and would not find himself suddenly balked, and with paralyzed initiative.

"The other problem—that of the

Games with underlying psychological purpose form an important innovation in the athletic programs of some of the eastern colleges. This game, "Who Am I?" constitutes an invigorating pastime.

women with nothing to do—is one of the most frequent and most serious with which the nerve specialist has to deal. These women, for the most part, are parasites; they have homes and husbands, plenty of means, and lots of time. They have no children, or else their children are grown up. They play bridge, go to teas or moving pictures, pour into the shops, wander about and watch the crowd, and in kindred ways make forlorn, undirected efforts to kill time. The best solution for these women is to find some work to do. They are ordered to seek their cure in gymnasiums, in public service in museums, and in courses of study.

"And right here," Dr. Dana interrupted himself, "I want to make clear just what I mean by recreation. I do not mean play, in any restricted sense of the word. Work may be recreation, when it is a change of occupation. In brief, a recreation, to be salutary, must be some occupation interesting and absorbing enough to drive every possible consciousness of work or responsibility from the recreator's mind. Of course, it must not be exhausting, nor rob one of proper sleep—that would be defeating its own ends.

"But to return to the problem of the idle women. I spoke before of those with homes and husbands. There is another class, consisting of the women who for one reason or another do not marry, yet who are economically free. Their salvation lies in finding some profession which will absorb them, and in becoming masters of it, not mere dabblers. I am strongly in favor of a bureau of occupations for such women, to provide them with the necessary recreation—for

that is what, in their case, such work would be."

In summary, Dr. Dana stressed again the importance of starting young, and of training the individual to give intelligent direction to his recreational activities. He spoke with praise of the aims of Community Service, Incorporated, whose representatives go into various communities and teach the members of them how to get together for organized recreation,

along lines of drama, glee clubs, sings, athletics, hikes, and a multitude of other interests sufficiently diversified to provide for all ages and temperaments. He concluded:

"When young folks are taught the worth and ways of recreation, they are taking out an insurance policy against nervous disorders; and in middle age, when they come to collect, they will find themselves reimbursed a hundred-fold."

Scranton Has Motor Dental Clinic

The School District of the City of Scranton has provided a motor dental clinic which travels from school to school. The motor clinic is equipped with electric lights, electric dental engine, dental chair, and table, sterilizer, running water, built-in cabinet, and standard instruments of a dental office. The clinic is heavily enameled in white, inside and outside. The work of the dental clinic is devoted largely to extracting, scaling, cleaning, and polishing the teeth of the children of the first two grades and to practical demonstrations of the need for oral hygiene. To date, more than 3,800 children's mouths have been treated.

The Work of the International Sanitary Bureau

The Gospel of Hygienic Living is Carried Over Racial Boundary Lines

By DR. L. S. ROWE, PH.D., DIRECTOR GENERAL, PAN-AMERICAN UNION, WASHINGTON, D. C.

THE International Sanitary Bureau, established in the Pan-American Union, was first organized by resolution of the Second Pan-American Conference held in Mexico City, 1901-2. Its state purpose was prompt and effective co-operation in all matters pertaining to sanitation and health throughout the American republics. It was provided by this resolution that the Governing Board of the Pan-American Union should call a general convention of representatives of the health organizations of the several affiliated countries in 1902.

This convention formed a permanent organization with headquarters at Washington, D. C., and invoked the cooperation of the United States Public Health Service. Since that year, conventions have been held in Washington, October 9-14, 1905; Mexico 1909-1910; Santiago, Chile, November City, December 2-7, 1907; San José, Costa Rica, December 25-January 3, 1908-1909; Santiago, Chile, November 5-11, 1911, and the most recent at Montevideo, December 12-20, 1920. To each of these the United States has sent delegates.

The whole purpose of the International Sanitary Bureau is the mutual and practical application of those theories and practices most generally advantageous for the health of the various nations. At the Montevideo convention it was agreed to place the work of the Commission on a more firm and stable basis, broaden its scope and add to its definiteness. To this end a special office has been opened in the Pan-American Union building at Washington, and is now in charge of a staff of special workers consisting of an Honorary Director and seven active members. All of the republics are requested to remit data relating to the sanitary conditions of their respective countries and to furnish every facility for a thorough and careful study of any outbreak of pestilential disease within their limits, so that the Commission may be able to lend necessary aid. A mutual exchange of information concerning special research, discoveries in medical science, treatment of special diseases, epidemics, clinical methods, and all

No nation can boast of a frontier that is germ proof, and sanitary defenses must be organized against imported as well as endemic diseases. Scientific sanitation, therefore, hinges upon the prompt and effectual international correlation of all facts pertaining to health matters.

The International Sanitary Bureau serves as a clearing house for all pertinent information, promotes the rapid interchange of advanced scientific thought, and fosters that rapport which enables the formation of a solid front against disease.

other matters of vital moment and sanitary value. Information concerning the existing status of preventable disease and progress reported, new outbreaks of contagious diseases, new measures for combating disease, demographic statistics, matters of interest relating to industrial hygiene, recent progress in child welfare, and matters of interest relating to water supply, drainage, and paving will be sent from the Washington headquarters to international sanitary authorities.

The Bureau will also endeavor to secure for such governments as may so desire, technical experts in the field of public health and sanitation and up-to-date detailed information relative to new sanitary processes. A mutual knowledge of each country's sanitary laws and regulations; the sanitation of cities and ports; prophylactic measures against plague, cholera, and yellow fever; measures for the destruction of rats, flies and mosquitoes; national and international protective and legislative measures relating to tuberculosis, venereal diseases, small-pox, trachoma, leprosy and scleroma; statistics of morbidity and mortality in the principal ports and cities, and information in regard to the adoption of the Bertillon nomenclature.

The work before the Commission is not only limitless in scope but inestimable in humanitarian value. With

the aid of the International Medical Congresses, the Scientific Congresses, and the Medical societies, its benefits will be world wide. The founder of scientific hygiene, Pettenkofer, once said that no frontiers could be made proof against germs. It follows, therefore, that the germs themselves must be eradicated. Further efforts toward the sanitary defense of the various countries must be made at their ports along the lines of the sanitary inspection of international maritime traffic, sanitary law on immigration, and quarantine treatment of imports and exports in order to guarantee hygienic safety and prevent commercial loss.

It is of vital importance that this interchange of international knowledge and sanitary procedure should be thoroughly understood and forcefully developed. With each stage of the advancement of methods of communication our boundary lines are becoming less definite in so far as the interchange of interests is concerned. To guard against the spread of this insidious enemy of mankind and to wage continuous warfare is a high and definite duty. Disease is no respecter of persons nor of localities nor races.

Nor can its control or eradication be accomplished by law alone. Voluminous of the wisest legal regulations cannot regulate mortality nor stamp out the penalties for careless living and disobedience to the laws of nature. Complete comprehension and enlightening knowledge only can eradicate individually that which collectively becomes an international menace.

The Sanitary Bureau, therefore, looks forward toward reaching the brain and heart of individuals. The exchange of medical students and internes between the hospitals of the various countries will give mutual insight into conditions, diseases and their treatments; the establishment of the nursing profession on as sound and scientific a basis throughout Latin America as it is in the United States will go a long way toward bringing into the intimacies of the home the gospel of hygienic living; and the fostering of clinics and visiting

nurses will still further popularize cleanliness and health.

It is expected that the Bureau will furnish a Bulletin of its own in the near future, as materials are organized and brought together, but for the present articles and suggestions will appear in the Bulletins of the Pan-American Union, the Spanish and Portuguese editions of which will shortly issue a special number on sanitation.

The officers of the International Sanitary Commission are as follows:

Honorary Director, Dr. Pablo García, Medina, Bogotá, Colombia; Director, Surgeon General Hugh S. Cumming, United States Public Health Service, Washington, D. C.; Vice-Director, Assistant Surgeon General J. H. White, United States Public Health Service, Washington, D. C.; Secretary, Dr. Julio Bianchi, Minister of Guatemala, Washington, D. C.; Ex-

ecutive Clerk, W. P. Montgomery, Pan-American Union Building, Washington, D. C.; Board of Directors: Dr. J. Llambías, Director General Public Health Service, Buenos Aires, Argentine Republic; Dr. Carlos Chagas, Director General Public Health Service, Rio de Janeiro, Brazil; Dr. Juan Guiteras, Director General Public Health Service, Habana, Cuba; and Dr. Luis Razetti, Academy of Medicine, Caracas, Venezuela.

New York Holds Unique Health Parade

MUCH in medical literature of recent months has had to do with child psychology. Mental tests, standards of mental devel-

opment, degrees and remediable features of delinquencies, psychotherapy—theories helpful, theories innocuous, theories distasteful—often inaccurate in generalizations and of remote application.

The recent health literature, on the other hand, becomes more and more concrete. Workers who are making first hand observations on the needs of the people are accumulating a wealth of material of definite value to other workers in the field. They are also learning the psychology of the popular mind, and esoteric speech is giving way to picture and drama that speak the universal language, and serve as direct incentives to action.

For, if the habits of a people are to be changed in the least degree their interests must be considered, their emotions stirred, and the psychologic moment of thought reconstructed on a new basis with the introduction of a new idea is being seized in educational health work to bring about a general appreciation that it is little matters which count

in a health program. The fitting of a house with the best sanitary appliances is ineffectual unless they are put to daily practical use. After all

These personifications of foods that are good and bad for children drive home the truth that milk, green vegetables, and ripe fruits must replace cheap cakes, tea and coffee.

Underwood & Underwood.
Vitamines mean nothing to the child, but "Egg," "Apple," "Orange," "Carrot," presented visually as adjuncts to health, have their appeal.

Underwood & Underwood.

Well cooked cereals, with plenty of foods containing the vital accessory factors, spell healthy and well ordered development for the children. Must health practices be enforced by spectacular appeals to reason?

Underwood & Underwood.

Plenty of sound sleep in well ventilated rooms, and the daily practice of individual cleanliness inculcated in the habits of the coming generation simplifies the health work of the future. The most effective work is with the children.

is said, public health is as effectual as an ideal as the general health practices of the people warrant.

Work becomes routine. More and more as it becomes an accustomed habit, the difficulty increases of introducing better practices to lighten the load. So do health precepts, too often reiterated, fall upon deaf ears. Hence the play instincts favor the introduction of new ideas. Prejudice

is in abeyance, suggestion finds ready acceptance, and changes in habit voluntarily assumed have a self-interest that fixes them as no outside force can do. The dramatic instinct helps. What a child "acts" out impresses him; the make-believe world of the child is one of the greatest formative influences in his character.

All of these considerations mingled with the creative instinct and the

spirit of pure fun in the recent pageant of good health factors in the health parade recently put on in New York City. The genius of many organizations combined to work out striking symbols and picturesque effects. The parade justified the adjectives freely used in its description, such as "monster," "gigantic," "gargantuan," and "huge," and it may be expected to bear definite results.

Human Efficiency and Levels of Intelligence

ONLY a pitiful handful of boys start in business with any special training for any industrial career, said Edwin S. Davis, chairman of the Board of Education of Chicago, in inaugurating Boys' Week on Friday, May 6. "We must give the boys a chance; our problem is to get them to accept education," he said.

The whole problem of inefficiency is surveyed from another angle by Henry Herbert Goddard in "Human Efficiency and Levels of Intelligence." "Whether thinking of children or adults," says Goddard, "in accounting for the large proportion of failures that are met with in society we have overlooked the relatively low mentality of the great middle group, the "C" group which in army tests accounted for 61½ per cent of the men who received the army mental tests." Men in the "C" group, he goes on to say, are rarely capable of finishing high school.

Goddard would prevent vast numbers of social failures by a predetermination of the unalterable mental level of each individual as "condi-

tioned by the inborn nervous mechanism . . . that is but little affected by any later influence except such serious accidents as may destroy part of the mechanism." He holds that "any attempt at social adjustment which fails to take into account the determining character of the intelligence and its unalterable grade in each individual is illogical and inefficient."

He expresses the conviction that every human being reaches at some time a level of intelligence beyond which he never goes; that these levels range from the lowest or idiotic, to the highest level of genius. The number of people of relatively low intelligence is vastly greater than is generally appreciated and this mass of low level intelligence is an enormous menace to democracy unless it is recognized and properly treated.

The failure to appreciate this fact and control it, has resulted in a vast amount of delinquency, and such delinquency impairs the efficiency of the total group to an extent that is little appreciated. The intelligent group must do the planning and organizing

for the mass, that our whole attitude toward lower grades of intelligence must be philanthropic; not the hit and miss philanthropy with which we are all too familiar but the philanthropy based upon an intelligent understanding of the mental capacity of each individual.

Due recognition of the low mental status of the average men and intelligent placement in the effort to care for badly adapted individuals is but a makeshift remedy. Too many social factors are operative in the causation of mental unrest to postulate that the mental limitations which obtain indicate inherent mental deficiencies. Not until the methods of training are universal which make possible the development of each individual to his full mental capacity may we conclude that 61½ per cent of the American people are incompetent to receive high school training. A big brain and the inherent power to react on a high psychic plane avail nothing for the individual if society does not take full advantage of the plastic period of childhood to develop to the utmost each individual member.

Public Baths Association of Philadelphia

By GEORGE L. HARRISON, JR., PRESIDENT, PHILADELPHIA, PA.

THE Public Baths Association of Philadelphia was organized in 1895, but it was not until April 21, 1898, that the first bath house at 412 Gaskill Street was opened to the public. In that year there were 21,656 bathers. From this small beginning, and a deficit of \$2,009.03, the Association has steadily grown until in 1920, with three bath houses, there were 474,201 bathers and a surplus from operations of \$14,347.32, after paying mortgage interest amounting to \$1,048.25 and keeping the property in thorough repair. This surplus is strictly from operations, and does not include donations or interest on the building fund. All surplus funds are turned into the building fund and a new bath house built as soon as possible.

Should Be Accessible

Our experience shows that a bath house should be situated on, or where it will be seen from, a main thoroughfare in a thickly populated section of the city, and the more people who pass by its doors between 8 a. m. and 4 p. m. the better, as in that case there are bathers all day and the plant does not stand nearly idle until the rush hours begin at 5 p. m. A plant should have about eighty baths in the proportion of five for men and one for women. One attendant can take care of from sixteen to twenty baths, and during the slack hours of the day these men clean the baths, wash the towels, etc. The plan of the baths is best shown from the illustration. The number of bathers in our heaviest summer month is about two and one-fourth times the number in our lightest winter month, showing how well the baths are used throughout the year. Originally the charge was five cents, for which was furnished a small piece of soap and one towel. Various changes, however, have been made from time to time, until now the charge is five cents for soap and towel until 5 p. m., after which time, and on Saturday, Sunday, and holidays, the charge is ten cents, but extra towels are five cents, and, while the towel furnished is sufficient, many take the extra towel, which accounts for the surplus from operations. No charge is made for children under ten years of age when accompanied by their parents. The time allowed in a bath is thirty min-

utes, for, although few stay so long, our bathers like to feel that they are not hurried. As the baths are kept very clean and attractive in appearance, our patrons are of all nationalities and many walks in life. We find the foreign born Jews among our best patrons. Boys and girls frequent the baths in considerable number, and many a newsboy will invest a nickel for a bath.

From time to time we are asked if we cannot make these baths free, or free on certain days. Our answer is always this: that even if the money were provided to run these baths free, we would not accept it, nor would we lower our prices. Our patrons are self-respecting people who have no other means of keeping clean, and most of them look on the baths as a business and want to pay for what they get. With this feeling they come into the baths as if going into a shop

to buy, and not with the shuffle of those going into a soup kitchen. Very little damage is ever done to our property through scratching names, breaking fixtures, or other malicious mischief. The city remits the taxes on our property and furnishes water at charity rates, which are one-fifteenth of the regular charges.

Pride in Cleanliness

For a number of years wash rooms were maintained in both the men's and women's sections, where our patrons could bring and wash their own clothes; but this was found to be very unsatisfactory, and the tubs were taken out and additional baths installed. We found the rooms were occupied by people of the lowest type, who drove away by their actions and foul language the other and more desirable occupants.

The Public Baths are open every

Bath House at 1203-1205 Germantown Avenue, Philadelphia, in which building nearly one hundred thousand baths were taken in the first two complete years of operation.

An interior view showing the arrangement of shower baths.

day in the year from 8 a. m. to 8 p. m., with the exception of Sunday, when they are open from 7 a. m. until noon. On holidays, such as Christmas, Fourth of July, Thanksgiving Day, etc., they are open from 8 a. m. until 11 a. m., and on Saturday they are open until 9 p. m.

I wish the readers of this article to visit the baths and see the constant stream of people that enters

our building, not with the slouch of the bread line and the soup kitchen crowds, but with the sturdy self-respect of those who pay for what they get and with the pride of physical cleanliness.

I have not spoken of the technical side of our Association, but shall be very glad to furnish any information on the subject; such seemingly small details as the height of the seat from

the floor and the swing of the doors add or detract much in the operation of the plants.

Health Service Bureau for St. Louis

The St. Louis Chapter of the American Red Cross has established a Health Service Bureau as a permanent activity in St. Louis. The bureau is located at 805 Equitable Building, Sixth and Locust streets. Its purpose is to act as a clearing house for health information.

The various activities it plans to carry out are as follows: (1) By the collection of information pertaining to health work in the city, through which any interested person or organization should be able to secure up-to-date information in regard to all phases of public health in St. Louis, not including personal medical service. (2) Through the collection of pamphlets, journals, etc., pertaining to health, it is the purpose of the bureau to afford assistance to persons seeking technical or non-technical information. Already over 800 magazines, pamphlets, etc., have been catalogued and filed for public use. (3) Through its publicity section the bureau is attempting to give to the public information on matters pertaining to health in a popular way, through publication, through exhibits, distribution of literature, etc. (4) By means of a speakers' bureau it will provide public health speakers to organizations and clubs desiring such service. (5) One of the most important activities will be a research bureau which will function at the request of existing organizations for the purpose of securing information regarding local health conditions. (6) The bureau plans to study health needs from the point of view of education and to meet such needs as are not being met by existing organizations, in various ways making health information as attractive and accessible as possible.

In brief, the Health Service Bureau has been organized as one of the fields of work for the public health department of the local chapter of the Red Cross. The Bureau will be under the direction of Dr. Borden Veeder.

In the past it has been necessary for any individual or organization desiring information regarding what is being done in a health way in St. Louis to make an investigation. All this information, now on file at the Bureau, will be immediately available and should be of the greatest use to the physicians of the community.

An eager crowd waiting for the Gaskill Street Bath House to open at seven in the morning.

Relation of Posture to Industrial Health*

A Chair Anatomically Correct May Still Fail Unless Fitted to the Work Place

BY EDITH HILLES, NEW YORK STATE INDUSTRIAL COMMISSION, NEW YORK CITY

IN A recent article on industrial seating, Frank B. Gilbreth is quoted as saying that the average factory chair reminded him of the time-worn story of the coffin: "The man who made it, didn't want it; the man who bought it, didn't use it; and the man who used it, didn't have much to say about it."

The principle aim in producing a seat for factory or store use seems to have been to make it unbreakable and so constructed that the salesman could with honesty claim that the chair would "never wear out."

Only now are manufacturers beginning to realize that a comfortable position at work saves energy units and means increased efficiency in production. Consequently, they are beginning to demand a chair for their workers which has been constructed with some knowledge of physiology, in addition to its "unbreakable" features.

The possibility for good posture at work has not been assured, however, when a good chair is secured. The relation of the different parts of the work place—the bench, chair, foot rest, the place for supplies and the

place for finished work—must be considered. The chair may be too high or too low for the work bench or machine, or vice versa. A brace or board, or a set of drawers may prevent a proper position of the worker's

slightly saddle shaped and with the front edge rounded; the feet resting comfortably on the floor or on a broad foot rest attached to the floor or bench; the bench at a height to allow plenty of room for the knees between the top of the seat and under side of the bench; no brace or other obstruction interfering with a comfortable position of the feet and legs; a back rest supporting the small of the back and not extending up far enough to interfere with free movement of the arms; supplies arranged so that no excessive reach is involved in the work. If an operator is able to rest herself by changing her position at work occasionally, a great deal of unnecessary fatigue can be avoided. For many operations, the thing to do is to begin by raising the bench and chair high enough to allow the operator to work sitting or standing.

There are now on the market or being tried out in laboratories, a number of chairs which have been constructed as the result of scientific study of how a physiologically correct seat should be made. The American Posture League have designed two chairs which they recommend for factory work.

Dr. Joel E. Goldthwait of Boston was the chairman of a committee that designed two chairs for the Massachusetts Institute of Technology in an

Barnet Phillips Company.

Chair approved by the American Posture League. It is made in four different heights, 16½, 17½, 19½ and 21½ inches, from floor to top of seat. The seat measures 16¾ inches wide and 15½ inches deep.

feet and legs. The management of a large plant recently decided to replace round-topped stools in one department with chairs which had been highly recommended. These chairs were pointed out to a visitor with great pride, yet the workers were all standing. It turned out that the work bench measured thirty-one inches from the floor, while all the chairs were twenty-eight inches high. It was an impossibility for the workers to get their knees between the chair and the bench, and the result was that these superior seats were never used!

The Principles Involved

Though in each individual case the type of work to be done must determine the best arrangements for sitting, the New York State Industrial Commission gives a general summary of the principles of correct seating as follows:

A seat, broad and not too deep,

E. E. Barney

A highly adjustable chair designed in the experimental department of a large typewriter company by Mr. E. E. Barney. The angle of the back rest adjusts automatically, turning on pins set in the two supports. The angle of the seat can be adjusted by pins that fit in holes in the legs of the chair. The curved foot rest supports the feet comfortably at all points.

Barnet Phillips Company.

High chair approved by the American Posture League. It is made in one height, adjustable from 27 inches to 35 inches. Width of seat, 14½ inches; depth, 13¼ inches; height of back, 12½ inches. Distance from top of seat to first slat of back, 7 inches. The chair is well suited to work at high benches where operators can either sit or stand.

Joseph & Feiss Co.

Chair designed by Dr. Joel E. Goldthwait's Committee for work which requires leaning forward. The seat is 16 inches wide by 13 inches deep, the shallow depth permitting the weight to be thrown forward and borne by the hips, the body bending, as it should, from the hip line. The first slat of the back is 5 inches above the seat level. Manufactured in one height—17 inches. As shown here, it is used with success by a large clothing factory.

effort to have the seating of the Institute as anatomically and mechanically correct as the details of the building construction. One chair was designed for lecture and reading work where the students could lean back; the other chair was designed especially for work which had to be done leaning forward. This seat therefore, peculiarly adaptable for use in many industrial processes.

It is encouraging that several commercial chair companies are now attempting the manufacture of seats which conform in many particulars to the best standards which we have, and which are a far step in advance of the still too popular "kitchen chair," or round topped stool.

Seat Materials

The most satisfactory material for a chair seat is wood. Cane seats are apt to become saggy and metal seats are too hard, or are made with sharp edges that cut off the circulation. The seat should be slightly saddle shaped and about sixteen inches wide. The best depth and tilt for the seat depends upon the type of work. The front edge of the seat is often a source of trouble; if it extends too far under the knees, the circulation is cut off; if the edge is left sharp and is not rounded carefully, this tends to cut off the circulation no matter what the depth of the seat may be.

1. California Industrial Welfare Commission. Bulletin No. 2a, Seating of Women and Minors in the Fruit and Vegetable Canning Industry in California. Harold Mestre, Sacramento, Government, 1919, p. 3.

The type of back which is most satisfactory for a seat to be used in a factory depends again on the nature of the work. Where constant lifting or reaching is involved, the back, unless carefully constructed, may interfere with arm movements. The California Industrial Commission in approving seats for women workers in the canneries, chose one with a rectangular seat and no back. In general, backs are used by workers and are recommended. Any chair which is to be used for rest, should, of course, have a back.

Where work can be done leaning

back, the American Posture League claims that there should be an open space about seven inches from the seat floor before the back rest begins. This will enable workers to sit well back in the chair. Support should be given at the small of the back and the support should be at least two and one-half inches wide and slightly curved. Sharp edges should be avoided and the horizontal supports should be spaced so that they do not pinch the worker by being too narrow or prevent the necessary space needed at the base of the chair by being too wide.

The Matter of Adjustment

The question of adjustment is a difficult one. To make a chair adjustable and still keep it within a market price tends to produce a light type of seat that breaks or becomes loose and wobbly, and serious accidents are not infrequently caused by the sudden breaking of a chair.

There is a great difference of opinion as to whether a chair should be made with adjustable parts or whether it is not better to construct it in different heights and sizes. Some chairs are made in as many as six heights.

There is again a great difference of opinion as to whether an adjustable chair should be constructed with tight nuts, etc., so that it could be adjusted only by a factory mechanic, or whether it should be constructed so that it could easily be adjusted by the operator by means of swivel screws, hand screws or pins. Some manufacturers claim that unless a chair can be adjusted by the operator,

A sliding seat arranged for a girl who is operating two collar ironers. The wheels and ball bearings of the chair move easily, but supply box is low and in bad position on right. The operator may work sitting or standing.

This turntable in a printing establishment has replaced a straight work bench, but the stools and supply heights are not satisfactory, foot rests are lacking, and supply heights are unsuitable.

it never gets adjusted at all; others claim that an operator does not know what the proper adjustment should be, and that as soon as he gets tired, he begins to meddle with the chair adjustments, so that the result is worse than a bad non-adjustable seat.

The crux of the matter is that the chair should "fit the worker," and give

his feet comfortably on the floor. This foot rest should never be fastened to the seat but should be attached to the floor or workbench and should be adjustable in height. A foot rest about

ten and one-half inches wide and slightly tilted toward the front is very satisfactory. A swinging foot rest with a broad flat surface and attached to the under side of the bench has been used with great success. (Reproduced in Figure 6 of the first article of this series which appeared in the May issue of *THE NATION'S HEALTH*.)

A narrow foot rest such as a lead pipe, the edge of a board from the rung of a chair is a make-shift and gives no real support.

Must Relate to Work Place

With most work places the bench height is stationary and it is necessary to adapt the height of the chair and foot rest to suit the individual worker. The first essential is that the worker sit with her knees and feet *under* the bench. If the bench is too low for this it must be raised. If a brace or bar interferes, it must be removed. The thickness of the bench top is an important matter. An overhanging support or brace may make it almost impossible for an operator to work effectively while seated. To fit the knees between the seat and the

A posture often seen which is productive of waste energy and fatigue on the part of the worker.

him the proper physiological support. Whether this is attained through a complex system of adjustments, or by constructing chairs in different sizes, is of minor importance.

Foot Rests Called For

A foot rest should always be provided where the chair is of such height that the worker cannot rest

Taylor Society—Mr. H. K. Hathaway.

The relationship of the parts to the work place has been carefully studied. The chair is on springs to avoid vibration. The operator works equally well standing or sitting. The seat, size, height, and slope have been given the individual work place. The trucks are made with units of convenient size for supplies, and the finished work placed in open side containers at easy height for the worker. The weight of the units is so regulated that a change of supplies comes at just the right time to relieve fatigue. Rest periods are also provided.

under side of the bench the operator is forced to sit so low that she cannot work properly; to sit high enough for work, she is forced to sit with her knees jammed *against* the bench and so is too far away from the bench to work properly.

A good height for a sitting-standing bench would vary according to the amount of strength needed in the operation. The height of sitting-standing benches shown in the report of the New York State Industrial Commission on Industrial Posture and Seating varies from thirty-three inches to thirty-seven inches. From six inches to ten inches should be left between the under side of the bench and the seat for knee space. A foot rest should be attached to the floor or to the bench and the chair should be arranged so that the operator can push it to one side when she stands at work.

Excessive reach for supplies or to stack finished goods should and can be easily avoided. To plan carefully the parts of the work place in their relationship to each other, is the most important task if good posture is desired.

In a rubber over-shoe plant, after a number of experiments had been tried, the following work place was standardized for the lasting department:

The bench is one inch thick, 37 inches from the floor, 42 inches wide, and a space is cut into the center 21 inches deep and 24 inches wide. The chair is placed in this cut out space and is of the type shown in Fig. 5. Height is adjustable from 25 to 31 inches, leaving at median height, 28 inches, an 8-inch space for knees. The foot rest is attached to the bench and is tilted toward the front, making a comfortable angle.

Supplies are kept on the right side of the bench and twelve racks, each holding four pairs of heavy wooden lasts, are kept on left side of bench. The operator while *seated* prepares all the lasts for soling, then she

stands and puts soles on the entire set of lasts. This latter operation takes about one-third of the total time.

Scientific American.
A curious "Chamber of Chair Horrors" collected in a large and progressive factory by Frank B. Gilbreth.

The "bent-double" position of the handfinishers in clothing factories can be largely corrected by proper seats

and benches for supplies. In one men's clothing plant where girls were working on buttonholes in overcoats, the heavy weight of the coats rested on the girls' knees, dragging off on the floor, as the buttonhole was made. Special supply trucks were put on casters, so designed that they combined a foot rest and a wide shelf where the overcoat could rest. These trucks were small enough to be pulled about easily. Although designed primarily to keep the coats from dragging on the floor, they proved even more successful in enabling the girls to work in a comfortable position.

The use of springs in the bottom of supply boxes or trucks is an ingenious way of avoiding tiresome reaches otherwise necessary as the piles of supplies diminish or increase in height.

California Standards

One of the most carefully worked out plans for good posture at work is that of the California Industrial Welfare Commission in its order on seats and work tables for women in canneries:

As far as, and to whatever extent, in the judgment of the commission, the nature of the work permits, the following provisions shall be effective; seats shall be provided, at work tables or machines for each and every woman or minor employed, and such seats shall be capable of such adjustment and shall be kept so adjusted to the work tables or machines that the position of the worker relative to the work shall be substantially the same whether seated or standing. Work tables, including cutting and canning tables and sorting belts, shall be of such dimensions and design that there are no physical impediments to efficient work in either a sitting or a standing position, and individually

Types of seats approved after installation, by the California Industrial Commission, for women in canneries. The height can be adjusted by pins that fit in holes in the seat support.

The inanimate equipment is everlasting; but what of the living worker?

Comfortable seating means safety for the worker and better output.

adjustable foot rests shall be provided. New installations are to be approved by the commission.

The *Bulletin* of the California Commission is well worth studying, as the

mentation. Like many details of industrial management, more is unknown than known, and there is no absolute standard. So little thought has been given to the problem of

A central office exchange of the New York Telephone Company. The chairs are adjusted to suit the individual workers. Foot rests are provided which do not show in the picture. In addition two rest periods each day are arranged during which the operators push back their chairs and stand at the board.

heights and dimensions are suggestive not only for canneries, but for all industries involving the same general types of work. The bench heights and arrangements for supplies would vary of course, according to the nature of the work—the strength and pressure involved, etc., but the California figures are the most definite that have been worked out for any specific industry, and may be modified and used in many instances.

We are still in the stage of experi-

posture in industry that at the present time almost any plant can go far in improving conditions by even the crudest attempt to plan the work place so that a fair chance for minimum posture standards is given the worker. This practice will result in general progress being made.

*The data in these articles were taken from the report of the Bureau of Women in Industry to the New York State Industrial Commission, on Industrial Posture and Seating. The illustrations used are from those courteously furnished the Bureau for their report.

Health Centers Aid the General Practitioner

The gradual change in the methods of diagnosis noted toward the latter part of the 19th century was outlined by Dr. Victor C. Vaughan before the Annual Congress of Medical Education, Licensure, Hospitals and Public Health held in Chicago March 10, 1921. Contrary to the popular notion that all notable achievements have been made in the medical centers, Dr. Vaughan gives credit where it belongs,—to the rural physician,—for the valuable contributions to science. Improvement of method and refinement of observation have ushered in a new era which requires facilities for diagnosis and treatment which is beyond the power of the recent medical graduate to acquire. These facilities,—library, laboratory, consultative service, so essential for diagnosis and treatment,—can be supplied through the health center. The needs of physician and patient were fully outlined by Dr. Vaughan, and he conceives as the best means by which these deciderata can be secured through the organization in every community of a community hospital, this community hospital to be supplemented by a tuberculosis hospital and such other agencies as may be required. Sixteen states have already enacted some kind of an Enabling Act for the construction of such hospitals. Such a hospital would be the center of hospital, laboratory and laboratory service to every legally qualified physician in the district. Preventive and curative medicine would be properly combined, collection of reliable morbidity statistics would be facilitated and it would afford the best possible way of placing all physicians in the community on the same level so far as opportunity is concerned, while at the same time it would give all citizens the benefit of scientific medicine, both preventive and curative.

Dr. Addison Retires from Office

The *Lancet*, London, of April 9, 1921, marks the retirement of Dr. Addison as Minister of Health, and he is succeeded by Sir Alfred Mond. The Ministry of Health was inaugurated in June, 1919, and in the beginning its labors were largely the amalgamation and re-arrangement of scattered duties discharged by six or seven bureaus separately, the majority having been the work of the Local Government Board and the National Insurance Commissions.

Programs for Venereal Disease Control

Popular Education, Individual Ethics, and the Strong Arm of the Law Unite in this Effort

By MILLARD KNOWLTON, M.D., C.P.H., REGIONAL CONSULTANT, UNITED STATES PUBLIC HEALTH SERVICE, DIRECTOR, BUREAU OF VENEREAL DISEASES, NORTH CAROLINA STATE BOARD OF HEALTH, RALEIGH, N. C.

THE venereal disease campaign that has been pushed so vigorously for the past two years has been an experimental excursion into an unexplored realm. Prodded by war necessity, the country and the various states have undertaken to follow the vision of a few forward looking men. The course has led through bramble and thicket, and we are not yet out of the woods, but slowly some of the fundamental things are emerging from the chaotic thought surrounding the subject.

Before the war, efforts for venereal disease control were spasmodic and intermittent. Here and there health authorities feebly called upon doctors to report their cases by number, and a few state legislatures were beginning to consider measures for dealing with the problem. The chief energies focused on the subject had been expended in propaganda by a few voluntary organizations. Thus, while the preliminary work of gathering and disseminating information and formulating speculative and theoretical plans had been under way for some time, there had been little practical experience in applying such plans to the actual problem of venereal disease control.

Health Officers Concerned

Accordingly, those of us who plunged into venereal disease work on a wave of war enthusiasm found a field unknown to be cultivated by methods untried. In proceeding from the known to the unknown it was but natural that the course adopted should be analogous to that pursued in the prevention of other communicable diseases. Experience soon demonstrated, however, that there were certain fundamental differences between venereal diseases and other communicable diseases that must be taken into account.

In the first place, all cases of venereal disease are not in communicable form and, therefore, all cases are not subject to control by administrative procedure of a health officer. Thus a case of syphilis of the central nervous system may give a positive Wassermann of both blood and spinal fluid

In every case of communicable disease the good citizen will, with proper appeal and sufficient instruction, refuse to endanger public health. Restrictive measures, however, must control the negligent or indifferent patient and publicity and police power must be enlisted on the side of public safety. Prevention, not cure, should be the slogan in venereal diseases, and administrative power commensurate with the importance of the office must be vested in the health officer.

yet not be a case to come under the jurisdiction of a health officer, for the reason that evidence cannot be produced to show that it is possible for such a patient to convey the disease to others. From a public health point of view it is necessary to make a clear distinction between a case that is infectious and a case that is not infectious. The health officer is interested in a case only so long as it is infectious and capable of transmitting infection to others. It is the health officer's business to prevent such transmission of infection. However much need there may be for a continuation of treatment until a clinical cure is effected, the health officer is officially concerned with treatment only until the patient becomes non-infectious. In making an examination of a patient to determine whether or not such patient is a menace to the public health, the health officer must determine two things: (1) the presence of venereal disease; and (2) whether or not the disease is present in communicable form. Action to protect the public health is based on the presence of disease in communicable form and not on the presence of disease *per se*.

Another and still more important difference between venereal diseases and other communicable diseases is that in the case of venereal diseases not all patients suffering from such diseases in communicable form are trusted so to conduct themselves as

menaces to the public health. In fact, very few patients will endanger the public health if properly instructed in methods of prevention unless, as in some instances, their occupations are such as will endanger others by the ordinary contact of daily life. Whether or not such a patient is a menace to the public health depends ordinarily upon his sex conduct. This introduces a factor which makes the venereal disease problem at once the most complicated, the most difficult, the most intricate, and in some respects the most important of all the public health problems.

The bearing of these differences between venereal diseases and other communicable diseases upon administrative measures to be taken for the protection of the public health is apparent upon a moment's reflection. Obviously, those cases that most concern the health officer are those that are most dangerous to the public health. Thus, reporting regulations that will result in having brought to the health officer's attention only those cases of venereal diseases that are dangerous to the public health will save his time in the investigation of non-infectious and trustworthy patients. If such regulations can be made to serve as a filter to catch only dangerous cases, the public health will be protected as well as if the health officer had to examine all patients suffering from these diseases. This end is attained by permitting the physician to report patients not dangerous to the public health by number without disclosure of name and requiring the name and address to be reported only in case the physician thinks the patient should come under a health officer's supervision for the protection of the public against his infection. Reports by number as well as reports by name are useful for statistical purposes.

Likewise, the invoking of quarantine as a measure to protect the public health will depend upon conditions outside the existence of venereal disease. In the majority of cases quarantine will not be required. Only in those infectious cases that cannot be trusted so to conduct themselves as

to avoid exposing others to infection will restrictive measures be necessary.

On account of the very complex factors involved, the method of carrying out quarantine procedure in venereal diseases must of necessity be different from the method of carrying out such procedure in other communicable diseases. In scarlet fever, for example, every case is a menace to the public health and, therefore, all cases are equally subject to quarantine. In such cases, quarantine can be carried out by isolation in the home. Most people wish to do the square thing, and the opinion of the neighbors is a powerful factor in preventing attempts to evade quarantine regulations when the house is placarded. In the case of venereal diseases, however, law abiding, responsible citizens who have had the misfortune to become infected may be trusted to avoid spreading the disease to others if they are properly instructed. Accordingly, restrictive measures to protect the public health may with safety be limited to those who would not carry out instructions, and who could not be trusted to avoid exposing others to infection while under treatment. Chief among this group of irresponsible people are the pimps and prostitutes. In applying quarantine to such characters isolation in the home has not been found effective. Forcible detention is necessary for the adequate protection of the public health.

There are other aspects of the problem in its larger relations that extend beyond the field of public health, and interlock with the duties of other officials and the functions of other departments of government. While the treatment of existing cases is now recognized as a primary necessity in order to render them non-infectious and thus not dangerous to the public health, it is clearly seen that treatment alone, without taking steps to stop the source of supply, is a good deal like the building of a hospital at the base of a cliff to care for those who fall over, instead of building a fence at the top to prevent them from falling. In the one case the hospital is a humane measure of cure, but it is more expensive and less effective than the fence as a measure of prevention. In the other, the necessity for treatment to render patients non-infectious would be greatly lessened by effective measures for the repression of prostitution which is the source from which venereal disease is obtained and passed on to innocent victims. The repression of prostitution is primarily the duty of peace

officers and court officials, but the law recognizes the relation of prostitution to the spread of venereal disease by requiring health officers to cooperate with other officials in performing this function. Such a broadening of duties greatly extends the horizon of the health officer and requires him to recognize and grapple with social problems as never before.

Of special importance in the promotion of any movement requiring public support in a popular government are those activities concerned with the dissemination of information usually designated as educational work. In the venereal disease campaign educational work is particularly difficult, owing to the relation of venereal diseases to sex conduct and the delicacy of the questions involved. Here, again, the things that must be done extend beyond the field of public health, this time into that of the school. Instruction concerning the contribution that sex makes to life and the physiology and hygiene of reproduction is distinctly an educational activity rather than a health activity. The health authorities are taking the initiative in this work because the educational authorities are not yet equipped to do so. The kind of educational work concerning this subject that belongs definitely to the health authorities is instruction concerning the ravages of venereal disease and the methods of cure, prevention and control. When the period of experimentation is over and the functions of the different branches of government with reference to this problem are more perfectly adjusted, the educational work will be divided between the health authorities and the educational authorities along these general lines.

The provision of recreational facilities as a preventive measure against venereal disease is mentioned here merely for the sake of completeness. While this line of work is important, it is not a health department function.

A Huge Experiment

Thus, the huge, country-wide experiment that has been carried on for the last two or three years, has resulted in fixing certain definite lines of activity as fundamental to any complete program of venereal disease control. These may be enumerated as follows:

- (1) Treatment of existing cases to render them non-infectious.
- (2) Administrative measures of control by the health officer.
- (3) The repression of prostitution

for the purpose of cutting off the supply of infection.

(4) Educational measures directed toward giving higher standards of sex conduct and disseminating information concerning the ravages and prevention of venereal disease.

These, then, are the principles underlying venereal disease control. In carrying out this program in North Carolina, clinics for treatment have been established in nearly all the larger cities and an active campaign is now being conducted among physicians to stimulate interest in the better treatment of venereal diseases.

The educational work is being developed along approved lines by means of lectures, exhibits, motion pictures, and an extensive distribution of pamphlets. Lectures are arranged for men and women separately, and the work includes a special educational campaign among negroes by a colored physician. More than half a million pamphlets have already been distributed.

The repression of prostitution by officials of local communities has been encouraged through the collection and presentation of information concerning vice conditions.

The final working out of the program of venereal disease control will include administrative procedures for handling individual cases dangerous to the public health. Among these procedures will be that of quarantine, for which ample powers have been granted health officers by the Legislature. The supreme courts of the states of California, Iowa, Kansas, Nebraska, Texas, and Washington have all sustained laws or regulations conferring powers of quarantine for venereal disease upon health officers. There have been no adverse decisions. Quarantine for venereal disease is thus placed upon a sound legal basis. A health officer's order of quarantine is not subject to judicial review unless fraud or bad faith is alleged. A person held under quarantine cannot be released on bail. Thus a health officer has more power than a judge of the court.

The greater the power the greater the dignity of the office. When the public comes to realize that such great powers are vested in health officers, the health officer will be given greater public recognition and appreciation. If the power vested in an officer be considered as indicating the importance of the office, then the whole cause of public health will be advanced by gaining such public recognition through exercise of the quarantine power.

Special Exercises for Special Needs

Exercise to Be Corrective Must Be Definitely Prescribed and Continuously Supervised

BY FLORENCE MEREDITH, M.D., PROFESSOR OF HYGIENE, WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA, PHILADELPHIA, PA.

GRANTING that the gymnasium may be used for individual therapeutics and, best of all, for disease prevention in the individual case, we have to consider how to determine what classes of cases require individual work, and what will do well in regular class work. It is unquestionable that the decision can only be made on the basis of individual examinations,—thorough ones, of all applicants for gymnasium work. The usual perfunctory examination of heart and lungs—often incomplete in that only the stethoscope is used—does not alone constitute a safer guide than the clinical history of the girl. After all possible facts are elicited, it will usually be clear whether the girl presents special needs. No one would think of performing a surgical operation without a thorough preliminary examination. No more should one lightly recommend the use of gymnastic exercise,—a measure which may have as much influence for good or ill as a surgical operation.

Study the Case

We believe that at the outset all beginners should receive at least a few evenings of individual work.

This is to get further data than an examination can possibly give as to the girl's requirements; to give the girl more confidence in herself as a gymnasium member; and to give her the confidence which results from the knowledge that her needs and limitations are understood. Many of these girls will require only such general exercise, ultimately, as may be given in groups, but need to have individual initiation in order that the amount and variety may be properly estimated.

Also, preliminary individual attention will discover those girls who have definite tendencies toward disability in various directions, who would not be in a position to have them properly guarded against in a class. These girls are often the ones who are underweight or overweight, who have poor posture, or weak abdominal muscles, who show a beginning relaxation of foot muscles.

Another class that is benefited by individual attention includes those girls who have conditions in which certain exercises can be used as a therapeutic measure; such conditions include constipation, dysmenorrhea, functional disturbances of the heart or the glands of internal secretion,

functional nervous disturbances, muscle and joint pain from improper use, poor lung development, poor circulation, somewhat increased arterial tension, toxemia from various causes, sleeplessness or sleepiness, the common type of moderate visceroptosis, flat feet, mental depression, including, of course, orthopedic conditions which are now commonly so treated, as scoliosis, etc.

The aim should be to get the girls of the first type into group work as soon as possible. We assign them to four evenings of special instruction and then, grading them as carefully as possible, put them into classes in other gymnasiums. The second class are kept until their tendencies toward illness have been sidetracked, no matter how long it takes. Results are what we are after, and if it takes one girl a whole season to get from the special instruction what she needs, the time is well spent. The girls of the third group are also kept until it is plain that they understand what they must do to keep in condition.

With each assignment for individual work a definite appointment should be made, spacing the time so that each girl shall have at least fifteen minutes personal instruction.

Fig. 1. Climbing stairs with back bent and chest contracted causes fatigue and breathlessness. If the body is kept erect, room is allowed for breathing and unhampered heart action.

Fig. 2. The correct posture in carrying a load is maintained either by shifting the load frequently or dividing it equally, thus avoiding a crooked back and a low shoulder. Correct poise makes for health and beauty.

Fig. 3. In walking the toes should point straight ahead for an easy gait.

After her physical examination, and before the hour appointed, the doctor and the physical director who made the examination should confer on her condition and together outline a series of exercises which seem suited to her needs. They should be under rather than over her ability, as the girl is likely to feel some soreness and become discouraged if at first she is permitted to overdo. The patient may also be alarmed at an undue increase in heart action and respiration, thinking she is being harmed. The exercises should be gradually increased, with frequent re-examination, if possible directly after

be familiar with certain abnormal conditions of heart action, and should be able to detect by appearance and pulse the necessity for further consultation with the doctor. The more capable the director is of doing this, the more confidence the girls will have in her and the better results she will get. Frequent changes of the series of exercises is the key to good success, or rather being ready to change them frequently, as the girl herself is better understood as time goes on and her needs change also.

Many more girls can be sent into the gymnasium under this system of individual work than could possibly be

they are not in the way of getting the greatest possible improvement.

The special exercises which we have found to be most necessary and are most frequently prescribed are those in which proper posture is developed, those tending to prevent and relieve constipation and dysmenorrhea, and those for improving foot conditions. Along with the former goes instruction in regard to clothing which will not be deforming or crippling, or which will not prevent normal functioning of all the muscles and structures of the body. With the second goes direction in regard to habits of ingestion and elimination. With the third, the whole subject of menstrual hygiene is explained. We try to adjust the minds of the girls to the normality of the function, doing away with the idea of invalidism. If organic trouble is found, as it seldom is, we try to get the trouble relieved by medical or surgical means. Finally, we endeavor to show the relation between good posture and general activity to the healthful functioning of the reproductive organs. In connection with foot troubles we emphasize the need of foot-shaped shoes.

The exercises used are largely based on the premise that proper posture and full muscular development and free circulation are essential to the normal functioning of any organ in the body. We lay especial stress on the development of the hitherto, in most cases, entirely unused abdominal and lumbar muscles. This weakness is not due entirely to the effect of corsets, as the condition is found as well in those who have never worn corsets. It is due to lack of education of these muscles, and hence lack of use. Since the relation of these muscles to poor posture is very close, and also since they bear a direct relation to lower abdominal and pelvic circulation, we endeavor to teach every girl their use, and see that she actually uses them. Poor position of viscera plus poor circulation through them is generally conceded to be a

Y. W. C. A.

Fig. 4. All foot exercises should be done in stocking feet or barefooted to allow full play of all muscles.

Y. W. C. A.

Fig. 5. Each exercise is to be repeated from ten to thirty times, resting after each five.

exercise. This is both to see the effect of the exercise and to reassure the girl about any symptoms which have frightened her—and patients of this type are usually frightened at something. Physical directors should be able to make examinations of back and feet and do measurements and strength tests. If they are not able to do this intelligently themselves, they cannot be considered competent to give exercises for the improvement of the condition. They need also to

sent into class work. We have great success in treating cardiac cases, chiefly functional and mild organic, and of disturbances of metabolism and internal secretion. Many of these cases, if doing definitely prescribed work under careful supervision, are safe and on the way to improvement. In a class, if safe as regards actual harm to themselves, which is not always the case, (although, as indicated above, I believe it is more often so than we think),

Y. W. C. A.

Fig. 6. Corrective exercises, the weight on the outside of the foot, for weak longitudinal arches is shown here.

Y. W. C. A.

Fig. 7. Which shoe will carry you to success in life? Certainly not the type of shoe which impedes circulation and hampers the use of the muscles.

Y. W. C. A.

Fig. 8. Foot circling is a strengthening exercise for weak transverse and longitudinal arches.

great factor in constipation and dysmenorrhea.

Since posture begins with the feet, we also begin with the feet in our attempts to improve posture. The putting on of good shoes fails if the feet are already deformed and crippled. We institute foot exercises whether or not we succeed in securing the adoption of better shaped shoes. Sometimes we postpone complete change in the style of shoe,—that is, for more than a short time every day, until the feet are in better condition to take advantage of the changes. But we hold the ideal before them of the perfect foot in the perfect shoe. Much can be done with even badly deformed and quite useless feet with this procedure, although, like other remedial measures, it does not always perform an immediate miracle, since the foundation of most troubles has been laid over a number of years. It certainly cannot be accomplished satisfactorily in classes, but at least must be begun individually.

It may be said that exercises for posture, constipation, dysmenorrhea and flat feet could be as well taught in classes composed of those afflicted alike, but such is not the case. In the first place, no two people are afflicted exactly alike. In the second place, since we are demanding definite results, we should make sure that each girl is doing the exercises exactly right, which can only be done if she is individually supervised. The exercise, if done wrongly, will fail and the method will thus be discredited in the mind of the girl with whom it fails, and her attitude towards it will extend ultimately to others. In the third place, there is great danger of putting a girl into a classification which indicates any form of ill health. It will be impossible for her to get it out of her mind that she is not a normal girl, her special needs being only temporary. She is likely to classify herself permanently as a case of such and such a disorder, definitely tagged. The mental effect of such identification with any abnormality is very dangerous, and is less likely to occur if little emphasis is put on this

aspect of the case, as can be done in individual work. There is no harm in emphasizing special needs; in fact, it has a wholesome effect in encouraging a girl to consider herself an individuality, and one for whom she is individually responsible. The attitude should be fostered that the girl is normal, with a few bad habits which need correction,—the bad habit of constipation, or headaches, or poor heart action, or unused feet. She should be made to feel that they are nothing more than habits which are within her control, as they always are to the extent to which we assure

educational; that is, we tell the girl what we are trying to do in ways that she will understand, and we "put it up to her" whether she will do the work which will make possible the desired result. None of the exercises will suffice if done only in the gymnasium once a week. They should all be employed understandingly and hopefully by the girl at her own home as often as they are prescribed. They should be recognized to be as definitely prescribed for her as would be a prescription to be filled at the druggist's, and that she is as much expected to take them and profit by

Fig. 9. Hand kneeling, swinging forward and back as a strengthening exercise for the great abdominal muscles, is corrective in menstrual disorders. Y. W. C. A.

Fig. 11. The knee chest position holding for three to five minutes night and morning is prescribed as a corrective in special disorders. Such simple means are an important part of a health regime. Y. W. C. A.

her she can help herself. Then, as soon as the proper steps are taken, so that it is evident that the bad habit is on the way to be permanently controlled, she should again be associated with other normal, normally living girls. The ideal form of exercise, after this end has been attained, is not formal gymnastic work in groups, except such special work as her individual needs may continue to require, but she then may have sports and stunts, supplemented in any case where it is necessary by the special exercises some individuals may need throughout life.

In all our work, we attempt to be

them as she would be if she were taking medicine. The attitude of "trying" this method of getting health, "to see whether it will help," should be discouraged; nor should the gymnasium shoulder the burden of producing results if the girl neglects all other forms of healthful living except the exercise. For example, the obese should not be treated with exercise exclusively in order to reduce weight. Almost without exception there is much besides that they must do and, if these other things are not done, the physical director would, in my opinion, be justified in refusing her assistance. A half-hearted interest in

self-development, or a halfheaded one, is little likely to show results that we will be proud of. Unless the girl sees the reason for what she is doing and is convinced that it is sound, provided she cooperates with nature in this direction, we can count on little improvement. With this understanding and cooperation, the limits of the utility of the gymnasium will be vastly widened, if we can have enough individual work.

Guide to Figures

These illustrations cover a series of exercises that were used at the New York Health Center for Women and Girls, conducted under the auspices of the War Work Council of the Y. W. C. A., of which Dr. Meredith was director.

Fig. 1.—Incorrect and correct methods of climbing stairs are shown.

Instead of climbing stairs with back bent and chest contracted (causing back fatigue and breathlessness) keep the body erect, doing the work with the legs and feet and thus allowing room for breathing and good heart action.

Fig. 2.—Correct and incorrect methods of carrying books or a load are shown.

Change your load frequently from one arm to another, or, if possible, divide it, thus avoiding a crooked back and a low shoulder.

Fig. 3.—The correct and incorrect manner of walking is pictured.

Walking is standing in motion. In walking the toes should point straight ahead and the arms should swing evenly at the sides.

Fig. 4.—Foot exercises recommended for transverse arch.

Position.—Stand with toes together, heels three or four inches apart.

Movements.—(1) Raise feet with toes together, keeping heels on floor. (2) Replace. Repeat from ten to thirty times, resting after each five.

Fig. 5. Foot exercises recommended for weak longitudinal arches.

Position.—Sit with feet parallel, and pull toes under forcibly. Replace.

Repeat from ten to thirty times, resting after each time.

Fig. 6.—Foot exercise for weak longitudinal arches.

Position.—Stand with feet parallel (A).

Movement.—(1) Raise inner border up and out, knees straight, toes and heel on floor (B).

(2) Replace (A). Repeat ten to thirty times, resting after each five.

Fig. 7.—A shoe to be correct (1) should have a straight inner border, because the foot is by nature straight on the inner side. (2) Must allow room for the toes by having an outside curve following the lines of the toes. (3) Must have a broad, low heel. (4) Should preferably have a flexible shank, because this allows the muscles of the arch to remain strong through use. (5) Should be low, allowing free circulation and use of the foot and ankle muscles.

Fig. 8.—Foot exercise for weak transverse and longitudinal arches.

Position.—Sit with right leg crossed over left knee, toe in with supporting foot, and bend up right foot.

Movements.—(1) Circle out to right, down, in to left, and up to starting position. Continue five times. (2) Reverse starting position, with left foot circling out to left, down, in to right, and up to starting position. Continue five times.

Repeat each exercise from forty to fifty times.

Fig. 9.—Exercise recommended for menstrual disorders.

Position.—Kneel on floor, bend forward until chest touches knees, arms stretched forward, hands resting on floor, shoulders distance apart.

Movements.—(1) Swing body forward and down to floor, straightening knees and bending elbows. (Return) to starting position. Repeat five, ten, or fifteen times.

Fig. 10.—Exercise recommended for menstrual disorders by Dr. Clelia Duell Mosher of the Leland Stanford University.

Position.—Lie on back on floor or bed, with knees bent, feet resting on floor or bed; hand resting lightly on lower abdomen.

Movements.—(1) Raise abdomen. (2) Relax abdomen. (3) Contract abdomen forcibly. (4) Relax.

Repeat rhythmically, without strain or jerking, ten times.

Fig. 11.—Exercise recommended for menstrual disorders. Painful, too frequent, too profuse, too long continued and irregular.

Position.—Take position as illustrated. Hold for three or five minutes night and morning.

Fig. 12.—Exercise for constipation.

Position.—Sit on chair with knees bent, feet resting on opposite chair or bench, two or three inches lower and twelve to eighteen inches distant, right arm folded low across abdomen.

Movements.—(1) Bend quickly forward, rounding back and pressing arm into abdomen. (2) Straighten back.

Repeat in groups of five, forty or fifty times.

Fig. 13.—Exercise for constipation.

Position.—Lie on back on floor or bed, with knees bent, feet resting on floor or bed.

Movements.—(1) Pull both knees to chest forcibly. (2) Replace.

Repeat in groups of five from ten to twenty times.

Fig. 14.—Exercise for constipation.

Position.—Sit astride on chair or stool, hands resting on thighs, body bent forward, back flat.

Movements.—Move trunk to left, upward, to right, and down, making complete circle. Continue without stopping five times.

Repeat, circling to right.

Repeat alternately from ten to twenty times.

Communicable Diseases

By HOYT E. DEARHOLT, M.D., EXECUTIVE SECRETARY, WISCONSIN ANTI-TUBERCULOSIS ASSOCIATION, MILWAUKEE, WIS.

IN THE light (1) of our newer concepts in regard to transmission of communicable disease; and (2) of the doubtful utility of present methods of placarding, I submit that the time has arrived for a complete revision of the common regulations and accepted practices of health departments in the matter of the placarding of communicable diseases, a suggestion which does not indicate any disparagement of the importance and value of isolation. On the contrary, it is inspired by a desire to see as many as possible of the handicaps which stand in the way of 100 per cent enforcement and acceptance of quarantine regulations removed, in order that we may be assured a maximum of protection.

During the period characterized by belief in miasmas or effluvia as the cause of communicable disease, the use of large placards with type which could be read at some distance was justified. Because of the doubt then existing as to the extent to which such contagion might spread from contaminated houses, there was a virtue in the adoption of a characteristic "danger color" scheme which would permit potential victims to receive warning at distances far greater than the printed words were legible.

Few sanitarians today, however, believe that the house which contains a victim of communicable disease is dangerous to its neighborhood. Few any longer believe the room to be so. Even the lay public is rapidly learning that it is the patient and not his surroundings that deserves close surveillance. And yet the placards continue to be printed in garish colors and insistent type faces to acquaint him who runs with the fact that his neighbor or his neighbor's child is under ban as a victim of a pest.

Today there is no good argument for the retention of such placards as we have known and still know. We

may prate upon the duty of the honest physician to report his patients in order that their homes may be placarded. We may continue our attempts to convince the victim of a contagious disease that he should be "socially minded" enough to submit graciously to the indignity; but in the back part of the minds of the family physician, of the patient, and even of the sanitary policeman, there is a sneaking feeling that the whole process needs apology. Because of this feeling, every conscientious party to the placarding is made more or less uncomfortable, and less conscientious physicians, patients, and health officials ignore or evade the responsibility or obligation.

The substitute herein proposed would be as effective a warning in the light of our present knowledge, as are the characteristic quarantine notices of the past—and present. In general, it would be more so, inasmuch as the incentive for evasion would be far less than now exists, for reasons stated.

My proposal is simple, viz., the use of plain small cards of the size and character commonly used over electric push buttons to apprise a caller that "the bell is out of order." Such a card would meet every legitimate need of the health department in giving warning. Its adoption would appeal to the reason and sense of fair play of victim and neighborhood. It would be "good psychology." Finally, it would put the department on the side of science by removing it from a position of tacit endorsement of hygone superstitions in respect to the transmission of communicable diseases.

Volumes are now written upon the effect of the mind on the body. Much of it is true, but I wish a little more was thought of the effect of the body on the mind.—Florence Nightingale.

The Veterinarian Contributes to Public Health

Veterinarian and Physician Are Complements and Allies in Scientific Research

By J. HOWARD BEARD, M.D., UNIVERSITY OF ILLINOIS HEALTH SERVICE, URBANA, ILL.

AN IRONICAL Nature has decreed—a thorn for every rose—that the best friends of man should be, potentially, his most dangerous enemies. When prehistoric man tamed the cat and dog, he obtained allies and companions whom he later worshipped, and whose fidelity furnished him a theme for songs and for stories with which he enriched his literature.

Faithful Fido and purring Tabby are objects of much deserved as well as much misdirected sentiment. They are delightful pets, but on occasion, take advantage of their intimacy to give man rabies, round and tapeworms, hydatid, the flea, and the tick. They play with his children and, as they have been cuddled up, they have mechanically and directly spread ringworm, favus, diphtheria, scarlet fever, whooping cough, and possibly measles and typhoid fever.

Man domesticated the horse, the cow, the goat, the sheep, and the hog which have fed, and clothed, and in the case of the horse and ox, have borne him from place to place. They have broken and fertilized the soil which has grown grains, vegetables, and fruits more abundantly. Yet these noble animals, when ill, have proved to be the worst enemies of man. They have destroyed him with tuberculosis, killed him with anthrax, cut him off with glanders, filled his muscles with *Trichinæ*, racked his body with Malta fever, and loaded his intestine with tapeworms. They may become so dangerous to him when infected with anthrax that their meat, milk, hides, hair, or bristles may cause his death.

That man should have some of the roses and avoid the thorns, that these best friends should feed and clothe him today and not destroy him tomorrow, is the contribution of the veterinary surgeon to public health. In his efforts to protect and to save animals, the veterinarian has consciously and unsuspectingly pointed to hidden paths by which man has been able to attain an average life nearer the normal limit of three score and ten.

The veterinarian has rendered a distinct service to public health by his diligence in preventing tuberculosis,

The invidious distinctions made in state appropriations for the protection of health and for safeguarding the animal industries find their explanation in the priority of departments of agriculture in getting definite information before the people, and public health education may be expected to develop a proper balance. Meanwhile, by his definite contribution to science, the veterinarian has shown himself not the competitor, but the valuable aid and ally of the physician in his battle against disease.

anthrax, Malta fever, rabies, glanders, pyogenic infections, foot-and-mouth disease, diphtheria, and trembles, diseases to which man and animals are alike susceptible.

Tuberculosis is very common in cattle and is becoming more and more prevalent among hogs. In every state in the Union the disease is present. In some states, the percentage may vary from 5 to 30 per cent of the cattle population; in others, investigations indicate that less than 1 per cent of the beef and dairy cattle are tuberculous. Nine per cent of the hogs slaughtered under government inspection during the fiscal year 1916 were in some degree affected with tuberculosis. The loss from tuberculosis is one of the heaviest taxes imposed upon the live-stock industry, amounting to at least \$40,000,000 annually in the United States.

Tuberculosis, in live-stock, is not only an economic loss,—it is a menace to health, particularly to that of children. More than one per cent of the total deaths from tuberculosis are due to the bovine bacillus. In young children approximately 10 per cent of the total deaths are caused by this type. The percentage tends to increase inversely to the age of the child.

The deaths, the sickness, and the suffering of man and animals, and the great financial loss incidental to bovine tuberculosis are entirely preventable. The use of the tuberculin test, scientific disposal of reactors,

prompt disinfection of the stables after removal of the reacting cattle, and the pasteurization of dairy products before feeding them to man, calves or swine, when uniformly done, will make bovine tuberculosis a pathologic curiosity in live-stock and in man.

Anthrax is as old as history. Moses describes, "a boil breaking forth with blains upon man and beast," probably anthrax. Homer, Seneca, and Virgil gave it a place in their poetry; and it attracted the attention of many medieval and modern writers. It was not, however, until 1849 that it was established that anthrax in man and animals is the same. In 1850 Rayer and Davaine noted the thread-like germ of the disease in the blood of dead sheep. During the next quarter of a century it was thoroughly studied by Pollender, Koch, and Pasteur.

Record of Human Anthrax

Perhaps the first recorded case of human anthrax in the United States occurred in Philadelphia in 1834. An epizootic of murrain broke out among cattle near the city and spread into the town itself. Several persons engaged in skinning animals developed malignant pustule. Louisiana suffered two epidemics, one in 1835, and a second in 1851. In this state the disease first appeared among the deer feeding on the salt marshes near the mouth of the Mississippi and subsequently attacked the cattle of the French planters. In 1865-7 there were heavy losses in Mississippi from anthrax. In 1853 a Massachusetts physician noted "a most singular disease, a malady known from remotest antiquity as prevailing in animals, but observed among mankind only within a comparatively recent period." In 1881 Dr. James Law wrote: "The transmission of this disease to man is far more frequent than is generally supposed." Anthrax was reported as having been present in practically every state in the Union by 1900.

It is necessary to glance at the history of anthrax to understand the extent of its dissemination, its possibilities for evil, and the public health problem it presents today. For the

decade, 1900-1909, there were 227 deaths from anthrax in the registration area which for this period included from 40.5 to 56.1 per cent of the population. It has been steadily increasing. In 1918, there were forty-three deaths due to anthrax in the registration area. During twelve months of 1919-1920, eighteen cases with nine fatalities occurred in New York City.

Most cases of anthrax in animals are attributed to infection from fodder, grazing on fields where carcasses of victims of the disease have been left, or through eating hay cut from such fields. Infected water, artificial manure, and imported foodstuffs are also frequent causes. Blood sucking insects may be a factor.

Man acquires the disease mainly through handling animal products containing the spores or bacilli. Persons engaged in transporting, unpacking, sorting and handling hides, hair, wool, bristles, horns or bones in industrial processes, are likely to contract the disease, unless precaution is taken to prevent it. Pulmonary anthrax is commonly known as wool-sorters' disease because of its appearance almost entirely among hair and wool handlers. Bites of insects, and even of pet animals that have fed upon diseased material may convey the infection. A number of cases have been reported due to the use of shaving brushes contaminated with anthrax spores.

As anthrax in man is secondary to that in animals, prevention is largely a problem for the veterinarian. Disinfection of all raw materials is essential in those trades which require the handling of hides, hair, wool, bones and other substances likely to harbor the spores and bacilli.

Sixty-three persons lost their lives from rabies in the registration area of the United States in 1918 and thousands of dollars were spent for Pasteur treatment. Hundreds of animals had to endure untold suffering and their deaths further increased the economic loss on account of this disease.

Veterinarians to the Fore

Hydrophobia is probably the most readily eradicated of communicable diseases. The infection is almost always due to the bites of dogs and the problem of prevention is the control of these animals for a sufficient time to cover the incubation period of the disease. The only measures necessary to obtain the result are: (1) a license for all valuable dogs and the destruction of all vagrants; (2) the

restraint either by a leash or better by an efficient muzzle of all dogs which appear in public places.

It seems inexcusable to permit this disease to exist causing terrible suffering to the affected animals, and menacing the lives of persons, particularly children on the streets. It remains because of misdirected sentiment and public indifference which are most amenable to education such as veterinarians and physicians can most successfully promote.

Foot-and-mouth disease is primarily a malady of cattle; secondarily an infection of man. It is transmitted to him through eating raw meat, uncooked milk products, or drinking raw milk. More rarely, it is acquired from the salivary secretions of diseased cattle reaching the mouth of man.

The local symptoms in man are not unlike those in cattle. Heat and dryness of the mouth are followed by eruption of pea-size vesicles over the lips, gums, cheeks, and edges of the tongue. The skin eruption appears mainly on the hands, tips of the fingers and base of the nails, it occurs less frequently on the toes and other parts of the body. The patient may complain of headache, pain of the limbs, cramps, diarrhea, weakness, and fever. The disease is seldom fatal and many mild cases are believed to be missed during the occurrence of an epidemic in cattle. Elimination of this infection in live stock or the pasteurization of milk at 60 degrees Centigrade for twenty minutes will protect man.

Milk sickness, commonly known as slows or trembles, is an illness of uncertain etiology, transmissible to man from cattle, through consumption of milk, milk products, or flesh of animals suffering from the disease. Little is known of the cause of trembles, although investigators have attributed it to—(1) a mineral poison; (2) a specific microbe; (3) to the ingestion of poisonous plants. The recent work of F. A. Wolf and his collaborators, has emphasized the poisonous plant theory of causation by presenting experimental evidence to show the relation of white snake root (*Eupatorium urticifolium*) to the occurrence of the disease.

Milk sickness in man is an acute, non-febrile disease characterized by marked depression, persistent vomiting, constipation, and frequent fatal termination. It is interesting, historically, as the cause of the death of Nancy Hanks, the mother of Lincoln.

Pyogenic infections, glanders, paratyphoid fever, sporotrichosis, and

actinomycosis are diseases of less importance of this general group to which both man and animals are susceptible, and from which he may be protected by meat inspection, pasteurization of milk, and measures to insure good health in domestic animals.

Man May Menace Animals

The veterinary surgeon has contributed to public health by caring for animals infected with diseases which occur primarily in man; secondarily in animals. Both cattle and hogs may contract human tuberculosis and later transmit it to man.

Cowpox and horsepox have been known for centuries. They probably originated with man and according to many expert opinions are modified variola or smallpox. In 1796, Jenner showed they are capable of producing an immunity to smallpox when inoculated in man. While the veterinarian has rendered distinct service in controlling these diseases in animals, in the case of man, more accidental inoculations would reduce smallpox among the unvaccinated without subjecting them to the danger of disfigurement of variola.

In rare instances, milkmen have infected the udders of cows with *Streptococci* or *diphtheria bacilli* and in this manner have caused epidemics of septic sore throat and of diphtheria.

The Host of Endoparasites

Veterinary science advances public health by stamping out endoparasitic diseases in live stock and in domestic animals, for which man may be the accidental, intermediary, or the only host. The more important internal parasites from the standpoint of public health, are *trichina*, *T. solium*, *T. saginata*, and *T. echinococcus*.

The *Tænia solium* has its encystic state in the hog, giving rise to what is commonly known as "measly pork." It may, however, undergo its larval form in man. In light infection the *Cysticercus cellulose* may be located in the connective tissues, muscles, or other tissues of man without giving symptoms and without discovery except at autopsy. In some instances the parasite may inhabit the brain, spinal canal, eye, heart, lung, or kidney and give rise to marked symptoms; in cerebral or cardiac infection it may cause death.

Fortunately, cysticercosis is becoming less frequent, due to decrease of the adult worm. This is the result of meat inspection, proper cooking, and better curing of pork. Hogs acquire the disease from human feces and from eating carcasses or offal.

The beef tape worm, *Tænia saginata*, is obtained from eating beef, particularly the tongue and the organs of mastication. Cattle acquire the disease by taking water or food contaminated with human dejecta.

While *T. saginata* may produce anemia in man, it does not present the danger of cysticercosis. Meat inspection, cold storage, and proper curing are gradually reducing the frequency of infection with this parasite. The encystic form dies in three weeks after killing, hence meat that has been preserved for twenty-one days may be considered safe.

Hydatid disease is an infection of considerable importance to both the physician and veterinary surgeon, as the larval stage of the echinococcus may occur in man, sheep, cattle, hogs, and dogs. The adult worm is found in the upper part of the intestine of dogs, wolves, and jackals. The dog is the chief source of infection. The gravid terminal segments of the worm are discharged in the feces of the dog and the eggs reach the intestine of man and domestic animals through contaminated food and water. Man may acquire the disease from hands soiled while petting dogs.

Trichinosis is due to *Trichinella spiralis*, a round worm, which may inhabit man, rats, or hogs. The common host of the parasite is the rat, which becomes infected in slaughter houses and butcher shops. Hogs get the disease by eating offal, rats, and possibly feces. The recent experiments of Raffensperger show that *Trichinæ* are not transmissible through the feces, unencysted forms are not capable of development when meat containing them is ingested, and the parasites spread from one host to another only as a result of the swallowing of meat containing the encysted larvæ.

The adult worm lives in the small intestine. The disease is produced by the embryos which penetrate the intestine, invade, and become encysted in the muscles. It is the migration of the embryos that give rise to symptoms, diagnosed as trichinosis.

Characteristic cases in man present signs referable to the gastro-intestinal tract, fever, severe pain of the muscles, edema, and leukocytosis, symptoms indicative of general infection. The disease is recognized by the clinical findings and microscopic examination of muscle tissue.

Trichinosis is preventable by proper curing and thorough cooking of pork. Pork products should be carefully inspected. Rats should be exterminated in slaughter houses, butcher shops,

markets, and places where hogs are kept. Offal should not be fed to hogs.

In the death of the rat man loses an unwelcome guest, who, on certain occasions, has dragged typhoid fever from the sewer to infect his host.

Animals suffering from septicemia, pyæmia, diarrhea or local suppuration are liable to be infected with *B. paratyphosus* or related bacilli and to furnish poisoned meat. Meat may be contaminated post-mortum from hands, butchers' tools, wrappings or other objects containing bacteria that may come in contact with it.

Meat poisoning is due more to bacterial growth than to the so-called ptomaines. Multiplication of bacteria and their dissemination are greatly favored by cutting and chopping the meat, and by warmth. This explains the greater prevalence of the disease in summer and its higher incidence among hamburger and sausage eaters.

The ordinary form of food poisoning gives rise to acute gastro-enteritis; the more severe cases show systemic symptoms. The great majority of the patients recover. Fatalities are comparatively rare.

Meat inspection affords little protection against the meat poisoning group of bacteria since they may pervade the meat and leave its appearance, flavor and odor unchanged. Animals known to have diseases likely to cause poisoning should be condemned.

Bacillus botulinus, an anaërobe, is capable of producing a highly poisonous exotoxin in food, especially in meat, nitrogenous vegetables, and ripe olives. Diphtheria and tetanus toxin and snake venom are harmless when swallowed, but the same is not true of botulism toxin. Exceedingly small amounts of this poison produce symptoms in twenty-four to thirty-six hours after its ingestion.

It has a predilection for the nervous system in man and exhibits itself by secretory disturbances and motor paralysis, particularly of the motor cranial nerves.

Botulismus is highly fatal and a very little contaminated food may cause death. Limber neck in chickens and certain forms of forage-poisoning are due to *Bacillus botulinus*.

The prevention of the disease depends mainly upon proper preservation of food, thorough cooking, and resistance to the temptation to taste food to determine if it is spoiled.

Successful treatment is difficult after symptoms are well developed, and the mortality is high. An antitoxin has been prepared which will

neutralize the toxin. A veterinarian, Robert Graham, has made valuable contributions to the study of botulismus and of the use of antitoxin in its treatment. With greater knowledge of botulism, earlier diagnosis will be possible and antitoxin should be more effective both as a prophylactic and as a therapeutic agent.

Discoveries in the field of veterinary science, with rare exceptions, have been helpful in the domain of medicine. Study of splenic fever in cattle and the demonstration of the relation of the tick to its transmission gave a new conception of the rôle of insects in the spread of disease and blazed the way for a better understanding of Rocky Mountain spotted fever, relapsing and South African tick fever in man. Investigation of surra in horses and nagana in cattle offered fertile suggestion in the study of human trypanosomiasis. Pasteur's immunization of chickens against cholera and cattle and sheep against anthrax are the forerunners of inoculation against typhoid fever, cholera, and plague. The world owes a great deal to the milkmaid who told the medical student, Edward Jenner, "I cannot take smallpox because I have had cowpox." Her information led to the discovery of vaccination which has saved millions of human beings from death or disfigurement. Incidentally it reduces the cases of cowpox among domestic animals.

The study of malnutrition, and its treatment in livestock and fowl has proved very helpful in dealing with scurvy, pellagra, rickets, and beriberi, and metabolic disease in man. Progress in animal feeding has usually created new possibilities for the better nutrition of man. Investigations of tumors in animals have shed additional light upon cancer.

The veterinarian's work with young animals has aided the pediatrician in feeding and caring for infants. Treatment of abnormal parturition and of post-partum illness in animals have in many instances offered helpful hints to the obstetrician which have extended the boundaries of his subject and in throwing greater safeguards around childbirth.

In the battle against disease, the veterinarian and the physician are complements and allies. The former strives to prevent sickness among animals and to protect man; the latter seeks to preserve the health of man and incidentally saves animals. The one alleviates the suffering of noble brutes; the other brings relief to his fellows. Both covet the glorious title of benefactor of humanity.

Vitamines as Factors in Public Health

VITAMINES, which formerly occupied a position of almost purely scientific interest, have in a surprisingly short space of time come to be a vital study in the foods of the Nation. Consideration of vitamins becomes a public health problem parallel with realization of what happens in their absence. The war experiences in all countries have shown what will happen to people *en masse* if these food substances are absent from the diet. Scurvy, beriberi, and rickets are probably the three best known diseases due to deficiency of the vitamins. It is indeed possible, but not probable, that other diseases may be due, at least in part, to similar dietary deficiencies.

Blunt and Wang, in the March issue of the *Journal of Home Economics*, discuss ninety-three articles, all of which have appeared since 1917, and most of them in 1919-1920. Their review, then, may be considered a critical analysis of the present knowledge of vitamins, and for that reason it will be considered in detail here.

Their material is considered under the headings of the three vitamins now recognized: Fat-soluble A—for a number of years known to be present in butter fat, cod liver oil, green leaves, and certain other foods—is necessary for normal growth and in its absence from the diet there often develops an eye disease known as xerophthalmia or keratomalacia; Water-soluble B—of fairly wide distribution in plants—is necessary for growth and also for prevention of polyneuritis or beriberi; Water-soluble C—the latest of the three to be recognized—is the antiscorbutic vitamin.

Deficiency Diseases

Fat-soluble A, the vitamin which apparently is the cause of the efficiency of cod liver oil, is necessary for proper development of infants. In Vienna since the war scurvy and also the eye troubles have developed from absence of vitamins. Rickets is certainly connected in some way with the lack of fat-soluble vitamin A, although it is improbable that a deficiency of this vitamin alone produces rickets. Low fat-soluble A, low calcium, poor protein, unsatisfactory salt combinations, acting together, may all contribute.

Regarding the occurrence of fat-soluble vitamins, although butter fat is still regarded as the most impor-

tant source, the quantity in the butter depends upon the quantity of A in the food of the cow and upon the manipulation of the butter. Whale oil, fish oils in general, fat fish, oleo oil, (and oleomargarine made from oleo oil), pig's liver oil, and liver tissue, kidney tissue, probably glandular organs in general, all have varying amounts. Many vegetables furnish rich sources; for instance, dried spinach, alfalfa, clover, timothy, and tomato. Carrots, sweet potatoes, yellow corn, although lower in A than spinach and alfalfa, all contain sufficient amounts for satisfactory growth.

A discussion of the generalization made by Steenbock that the foods which contain this vitamin also contain yellow coloring matter is entered into by Blunt and Wang, and it appears reasonably safe, they say, to assume that the fat-soluble vitamin is a yellow plant-pigment or a closely related compound.

Are fats or merely the fat-soluble vitamin necessary in the diet? Osborne and Mendel have made use of their dried alfalfa with its very high fat-soluble vitamin and very low fat content to study the question of true fat requirement. They found that their young rats thrived on a diet of dried alfalfa, yeast, starch, meat residue, and salts,—that is, a diet almost free from true fats. "If true fats are essential for nutrition during growth, the minimum necessary must be very small," they say.

Regarding the stability of the vitamin content, there seems to be considerable discussion as yet. Heat seems to be an important cause of the destruction of the Vitamin A.

For studying the water-soluble Vitamin B, observations have been continued on the growth of rats and on the onset of polyneuritis in pigeons and chickens. While it is not definitely proved that these two methods deal with one and the same substance, the assumption that such is the case is usually made. During the past year, however, evidence has been adduced by Emmett and Luros that two distinct substances may be involved, for a sample of unmilled rice heated to 120 degrees for six hours had ceased to be satisfactory for preventing polyneuritis in pigeons but was still satisfactory as the only source of water-soluble vitamin for growing rats.

The occurrence of this water-soluble B is less in animal than plant

foods, such as, for instance, the seeds of cereals and a number of legumes. Spinach, cabbage, potatoes, and carrots, the edible portion of the onion, turnips, beets, and tomatoes, immature alfalfa, clover, and timothy show decided advantages over the mature. Fruits are also rich in B, such as orange, lemon, and grape fruit juices. One of the most interesting and important facts, which is often overlooked, relates to that part of the cereal which is not rich in B, namely, the bran. The amount of B in commercial wheat bran depends entirely on the amount of germ associated with it.

Osborne and Mendel are cited as having determined that yeast is distinctly the richest known source of the water-soluble vitamin, being four times as efficient as dried spinach, which ranks next among a group studied quantitatively. Only half as rich as spinach are whole wheat, soy beans, dried eggs, milk solids. Cabbage, too, is not so satisfactory as spinach. Abderhalden has succeeded in protecting pigeons, fed on polished rice, against polyneuritis by such minute daily amounts of yeast as 0.05-0.01 gram.

Regarding the stability of water-soluble B, again there is dispute, but results point to the safety of water-soluble vitamins in ordinary cooking processes, but the danger of its destruction in commercial canning or high pressure cooking. Tinned meat is devoid of vitamins, as was proved by the development of beriberi in the British army in the Dardanelles and Mesopotamia. A relation seems to exist between the water-soluble vitamins in the diet and the amount of food eaten.

The results of the lack of B have been well studied. There was little difference between the group undergoing B starvation and that with general vitamin starvation. "Perhaps one of the most remarkable results of a dietary deficient in so-called anti-neuritis vitamin is the constant and very pronounced atrophy of the testicles in males and the similar but less pronounced atrophy of the ovary in females." Other investigators have noted similar results of vitamin starvation. Drummond found that when male rats after as short a time as fourteen days on a diet adequate except for B were mated with females on an adequate diet no pregnancies resulted. Vitamin B also had a defi-

nite effect on infant nutrition, which shows an improved development when proper amounts are fed.

Water-soluble C is an antiscorbutic vitamin. Chick is quoted as saying, "The vitamin is present in living vegetable and animal tissues, in largest amounts in fresh fruits and green vegetables, to a less extent in root vegetables and tubers. It is present in small amount in fresh meat and milk, and has not been detected in yeast, fats, cereals, pulses." Many vegetables possess this vitamin more readily than the fruits; for instance, raw cabbage, raw swede—which is a kind of turnip—beet root, carrots, and raw or cooked rhubarb. Cooking, however, in most instances diminishes or entirely destroys the efficiency of the vegetables except when they are young, although canned tomatoes are a most serviceable antiscorbutic for artificially fed infants. Canned tomatoes contain all three vitamins.

One more human scurvy experience is cited to illustrate a number of points so far stated. A number of South African Native Labor Corps were established in France during the war. The rations consisted of one pound frozen or preserved meat, eight

ounces fresh vegetables, and definite quantities of mealy meal (corn) or rice, bread, coffee, sugar, salt, margarine, and tobacco. In county depots where they could pick extra fruit (apples) no scurvy occurred, but in a camp when this was impossible, 40 per cent of the natives at one time showed symptoms of scurvy. The half pound of fresh vegetables probably allowed no margin for the reduction of the antiscorbutic, and yet all foods had been cooked for at least three hours. The chief parts of the cure was to give lemon juice, increase the supply of fresh vegetables, and limit the period of cooking to forty-five minutes. In a camp where the scurvy was most severe and lasted longest it was discovered that the instructions to shorten the cooking period had been disobeyed. The condition was soon improved when the cooking was reduced to forty-five minutes.

Conclusions Stated

It is plain that remarkable as are the advances in the subject, we still have far to go for anything approaching complete knowledge. We need more quantitative information as to the distribution of the vitamins in foods and their resistance to all sorts

of manipulations—cooking, storing, aging. We lack knowledge of the quantitative advisable for human beings of different ages. Finally, and most fundamentally, we yet await the isolation of the substances themselves in purity and the establishment of their chemical composition.

It is very difficult to say what is the importance to the average individual of giving thought to these three vitamins in choosing the diet. Most of us probably use milk or leaf vegetables—McCullum's "protective foods"—to get an adequate supply of A, enough vegetables of all kinds and whole cereals to get B, enough uncooked or little cooked foods for C. But the occasional moderately well-to-do individual with dietary idiosyncrasies, many persons on very limited incomes, and many institutions must be close to the danger line. Probably C, with its marked instability to heating or drying, is the most often low in quantity, and A, with its limited distribution, second. It is more than probable, too, that many of the more obscure disorders and all sorts of common languors and inefficiencies and susceptibilities to many miscellaneous infections are connected with shortage in vitamins.

Chicago Holds Pageant of Progress

PROGRESS has usually been regarded as the direct sequel to the creative imagination of comparatively few advance thinkers whose ideas, projected into the future, visualized some objective toward which the populace was thereby encouraged to aspire. Some have held that even the occasional genius is es-

entially the product of his time, and that progress results from the collective thought of the whole people,—that somehow, somewhere in the process of collective effort there evolves a better vision than would be possible to any single member of the group.

Both arguments are in a measure

right, but in the consideration of the whole subject some confusion arises in regard to what really constitutes progress. One of our leading sociologists has written a huge tome, the purpose of which is to define progress and to furnish a yardstick to test out real values in many of our so-called advances. Is there at any time any conscious striving on the part of *all* the members of a given society toward the goal of the common welfare? Is the continuous change of opinion and action necessarily progress at all? By what criteria are we to know whether current opinion and action are constructive?

Chicago is attempting to answer some of these questions in her "Pageant of Progress," set for July 30 to August 14, 1921, to be held in the Municipal Pier, which is said to be the largest exposition building in the world, and the project is said to be the first in which an exposition of this kind has been planned on a non-profit basis,—the whole proceeds being devoted to public welfare and to publicity for the development of further work of the kind in the future.

Practically every industry—local

Chicago's Municipal Pier will be the site of a sixteen-day Pageant of Progress, July 30 to August 14, 1921. The Pier is the largest exposition building in the world, having a total exhibition area of about four hundred thousand square feet. Municipal Pier recreational activities constitute regularly a phenomenal achievement in civic welfare.

The sixteen sections of the Pier, each three hundred feet long, have been set apart for special industries and groups of industries. Here will be represented all trades and industries, machines, inventions and scientific achievements.

The Municipal Pier was constructed with a definite civic purpose; it has become a definite factor in community life. It fittingly houses an exposition devoted to the promotion of public welfare.

and general—will be fittingly placed in order to set forth its special claims as a contribution toward social advancement; but it is in its health phases that the scheme is unique. Plans have been made to construct a glass house 110 feet in length, costing five thousand dollars, in which the examination, measurement, and classification in the prize baby contest will be carried out in full view of the public. Babies from the five states of Illinois, Indiana, Iowa, Michigan, and Wisconsin will be entered daily, the winning babies chosen by the end of the fourteen day period of the Pageant.

An exhibit of welfare work by several bureaus of the Department of Labor will be made in which the education of aliens to the need of naturalization, child welfare, and women's industrial work will be presented. The Secretary of Labor, James J. Davis, is an enthusiastic supporter of the Pageant of Progress Exposition.

The Loyal Order of Moose has also taken a space on the Pier to set forth the splendid work of that order through its naturalization and immigration bureaus, and its vocational department.

Three branches of the United States Government have expressed practical interest in the educational value of the Pageant of Progress Exposition. Mr. M. H. Leopold, safety engineer of the Bureau of Mines of the Department of the Interior, will demonstrate the value of the rescue cars used by the Department of Mines. The cars contain all the latest safety devices and a glass enclosed chamber, in which rescue crews operate in poisonous gases, will also be exhibited.

Dr. C. F. Bolduan, chief of the Section on Public Health Education of the Public Health Service, will make an exhibit of health service work in

combating malaria by mosquito extermination, rat-proof buildings to prevent plague contagion, and occupational hygiene for shell-shocked soldiers and tuberculous patients.

Exhibits especially pertaining to health will include: Milk Products Sections; Food Products Section; Public Safety Section; Safety First Section; Laundry and Sanitary Appliance Section; Chemical and Drugs, Medical Science, and Dental Supply Section; Agricultural and Mining Section; and Children's Section.

Especial value is given to the several exhibits by the manner in which educational and industrial achievements are linked together in each of the sections. Eminent educators and scientists have given thought to the psychologic appeal and will create in each section an exhibit which will interpret the activities of each sectional exhibit to the public by a special display, and will show the part which the colleges and universities are taking in the preparation of the younger generation to assume leadership in these industries.

Comparative values should be brought out in the several lines of human endeavor, and especially in this greatest health show the cumulative social value of intelligent co-operative effort will receive new emphasis.

Connecticut Makes Survey

The Commissioner of Health of Connecticut has a plan for an intensive rat survey to determine what steps are necessary to protect the ports and cities of Connecticut from an invasion by bubonic plague. The plan was disclosed in a hearing on the health bill supported by the state health committee and appropriating \$30,000 for the work.

Rat Eradication Pays

C. E. Hauer, chief sanitary inspector of the United States Public Health Service, in a recent *Public Health Report*, outlines a guide to the proper rat-proofing of buildings. The destruction of the rodent population, as far as possible, is a measure of primary importance in any district where bubonic plague is present, because the plague is primarily a disease of rodents, and secondarily a human infection.

Rat eradication is usually carried out in three ways: by intensive trapping, poisoning, and rat-proofing all buildings. The first two measures are important in the early operation of a campaign.

No community thus far has been absolutely free from rodents and the most that can be expected is to keep the rodents at an irreducible minimum. The writer suggests the passage of a rat-proofing ordinance, with the supervision of work by a man familiar with the habits of rats and a thorough knowledge of construction work. He outlines various methods of rat-proofing buildings, food depots, and all places where foodstuffs are stored, handled, or prepared, and residences, and all other buildings not in the former class. The most effective way of treating buildings, from his point of view, seems to be to install a concrete floor, properly protected by an area wall. All lumber retained on premises should be elevated on racks two feet above the ground, roof openings should be closed by proper screening, and above all, it is important that garbage be kept in metal containers with tight-fitting metal covers. All drains should be screened with cast-metal grating. Concrete used should be very carefully mixed because defective material seems to be no protection whatsoever.

Spring Planning of Summer Health Campaigns

NOW that the novelty of having a voice in municipal and national affairs is beginning to wear off somewhat, women are turning serious thoughts to many problems of public health which men seem rather to have slighted in the past. There is perhaps no division of public health work which has quite the same appeal to women as that pertaining to Child Welfare, and their record of achievement in this branch is indeed a notable one. In order that infant mortality may be still further reduced and the success of child welfare work assured, we must have organizations to raise funds, plan the work, carry on propaganda, and consider the problem in its broader aspects. We must have social workers and volunteers to help carry the word into the homes, educate the people into seeking advice, and create a proper health atmosphere. And, finally, we need those self-sacrificing, hard working, tactful angels of mercy, the nurses, who go into any and all kinds of homes, risking insults and worse, and while bathing the baby or preparing its food, deliver short lectures on subjects pertaining to hygiene, sanitation and home economics.

This is the season of the year when the need for such efforts is most acute, when infant mortality is on the up grade. Every community, no matter how small, should have definite plans perfected for aiding in this work, and it is just here

that the women can assist in educating the general public in the saving of hundreds of little lives. Suggestions as to scope and management of such a campaign may be had from the Federal Government or the various child welfare organizations. As a suggestion we might mention the need of covering, by means of lectures, newspaper articles, posters, and clinical conferences, some or all of the following points: The importance of breast nursing, the care of the baby in summer, the protection of young children from infectious diseases, the study of causes and treatment of malnutrition in children, regular examinations of children of school and pre-school age for remediable defects, immunization against smallpox and diphtheria, pre-natal care, etc.

Of course efforts such as we have outlined need not be confined to one sex or the other,—but when all is said and done, the health and development of our children depend first, last, and always, on the women.

A National Department of Public Welfare Now Assured

A DEPARTMENT of public welfare with a secretary in the President's cabinet will probably be created as a fulfillment of party pledges. To this new department will be transferred several of the existing offices, boards and bureaus which deal with health, education and welfare.

If the law creating the new department succeeds in making a practical distribution of federal work among the departments, it will have general support. If it merely regroups certain offices and boards in the new department without disentangling the present chaos, it will serve no purpose except to provide additional patronage. Health work is now scattered in every department without any central coordinating machinery. Educational work is also developed in almost every department. We greatly fear that political and personal influence will be exerted to prevent the full consummation of the purpose for which the new department is supposed to be created.

Compensation for Disease Incident to Occupation

IT IS probable that in the near future occupational diseases will become compensable in most states. Laws to this effect have been passed in New York and California and are just now in process of legislation in Ohio. With this precedent, it is only a matter of time before the compensation laws of other states will be changed so as to include in the definition of the word "in-

jury," disease due to, and arising from, occupation.

The average physician, including the average industrial physician, is lacking in anything like a thorough knowledge of the specific industrial poisons and their effects. The field is so large that perhaps this is not to be wondered at, but at least it is fair to insist that the industrial physician be familiar with the occupational diseases of the industries he serves. Once these diseases become compensable, not only must he be able to recognize them, but know how to treat them and how to overcome them and prevent their recurrence. His duty towards his employer can demand no less. Furthermore, he must maintain the highest standards of his profession by recognizing these diseases fairly and squarely when brought into contact with them. To gloss them over, minimize their effects, or to deny their existence from a mistaken idea of duty owed to his employer can only work injustice to the men intrusted to his care, lower his self-respect, impair his usefulness, and do the industry no real good.

Arriving at a diagnosis is often fraught with difficulties and pitfalls. Where the matter of compensation is involved, the possibility of confusion is increased even in the absence of intentional dishonesty. By handling these cases with entire open-mindedness and candor the industrial physician will earn the confidence of all parties, his diagnoses will be accepted, and much dispute and ill feeling avoided.

Up to this time, laws bearing upon the occupational disease have specified only definite occupational illnesses such as lead or arsenic poisoning. Concerning even these fairly well defined diseases there is not sufficient general knowledge, and in reference to the large number of poisonous substances arising in and from the dye industry, the lack of precise knowledge along the lines of industrial toxicology is formidable.

It is quite possible that in time the law will attempt to define the responsibility of industry for diseases with a less obvious industrial etiology. Much has been published, for instance, of the prevalence of tuberculosis in various industries.

All of this emphasizes that the ultimate success of industrial physicians and hygienists lies in a thorough knowledge of working conditions. If occupational disease laws are to be justly applied, then the industrial physician must be the arbiter and specific knowledge gained by study and actual experience is the one qualification that will entitle him to jurisdiction.

A. J. LANZA, M.D.

The National Health Council Now at Work

THE National Health Council, composed at present of ten member organizations, which were listed elsewhere in this magazine, has accomplished through the formation of a coordinating body not only a time and energy saving device for the administration of health matters, but it has, through the concentration of the offices of the member organizations, multiplied their influence by thus becoming accessible to workers who visit New York. manifold possibilities suggest themselves in the way of better coordinated programs through such conferences and as an outgrowth of the information service maintained. From the Washington office an information service is being supplied the members on national health legislation, while in New York a general information bureau on health organization plans, resources, and activities, is being developed, which will enable other services to follow the successful establishment of these initial projects.

The Public Health Council, representing as it does many prominent national health agencies, should afford invaluable service as a clearing house and coordinating center in many fields where common functions are performed. It will become an integrating force among independent, autonomous agencies, rather than a merger of such agencies into one organization. Such a movement, through its membership, and through a mutually helpful relationship with state and local voluntary health agencies, should effectively serve the declared object of the National Health Council, which is, "the betterment of health work in the United States."

Are Health Departments Strictly Logical?

THE statement that "it is very probable that there is as yet no municipal or state health department which is organized along strictly logical lines," is made by Dr. Charles V. Chapin, veteran health officer of Providence, in the December issue of *New York Health News*. Dr. Chapin has been aiming to ascertain the relative values of different forms of public health work in order properly to marshal the forces against disease and ill health with the greatest effectiveness. The charge which Dr. Chapin makes against public health administration in this country, though severe, applies with equal force to practically every other governmental activity, whether it be educational, fire prevention, or

police protection. It must be admitted, however, that efforts to make our health program more logical and consequently less wasteful are bound to have their effect on the future health department organization. Tradition and politics are the two causes assigned by Dr. Chapin for the present state of health organization inefficiency.

Some years ago the American Public Health Association estimated that adequate health protection for a community would necessitate an appropriation of fifty cents per capita. In 1911 Dr. W. H. Park of the New York City Health Department estimated that from fifty cents to one dollar is required for community health protection. With the rising cost of labor and the present cost of other commodities these estimates are probably too low.

For example, comparison of per capita expenditures of the various municipal activities, in Oklahoma City, made by Horwood and Schevitz, revealed the fact that while \$4.00 per capita was spent in 1917 for education, \$1.92 for water, \$1.01 for fire safeguards, and \$0.78 for police protection, only \$0.20 per capita was spent for health conservation. While these figures indicate the relatively small appropriation for health protection, on further examination it was found that two of the largest items in the health department appropriation were for the care of patients at hospitals and for cutting weeds, neither of which can be considered proper expenditure for disease prevention. It is obvious therefore that in addition to directing attention to the proportionate size of the health department appropriation, it is exceedingly useful to analyze the expenditures for the various measures employed in the public health campaign.

Studies made by Franz Schneider, Jr., of the Russell Sage Foundation, Meader and Brooks of New York, Chapin of Providence, and Olesen of the United States Public Health Service relating to the evaluation of health activities, are significant in their similarity of ratings of the more important public health measures. The use of a score card is recommended by Olesen in a recent issue of *Public Health Reports* because "it stimulates the health officer to increased activity, points out the relative importance of the various branches of public health administration, and provides a means of self-measurement." The score card possesses a serious defect, however, in that it provides no means of measuring accurately the result of the health officer's activities.

On the whole, it can be expected that these attempts toward critical examination of our methods and programs will be reflected in a greatly improved and increasingly effective health machinery.

What We Can Learn from Framingham

BETWEEN four and five million dollars are spent annually by private agencies alone in the campaign against tuberculosis and an equal if not larger amount is spent by official departments for the same purpose. It will be readily recognized that the undertaking of an experiment such as the Framingham Tuberculosis Demonstration was well advised not only from the standpoint of research, but from a business standpoint as well. It is expected that the application of the knowledge and ideas gained from the Framingham experiment on relative values of the different measures in the anti-tuberculosis fight will many times repay the small cost of this community study.

Planned originally for a period of three years, on the recommendation of the special Appraisal Committee the Metropolitan Life Insurance Company provided funds for the continuance of this study for another three years. Four years have gone by since the inauguration of the Demonstration and it is profitable to summarize at this time a few of the more significant lessons taught us thus far. Of course these observations are not entirely conclusive, yet they are indications of sufficient strength to warrant their earnest consideration. To what extent do the Framingham findings answer the questions we are constantly asking on the validity and direction of our present anti-tuberculosis measures?

In a paper outlining the methods and accomplishments of the Framingham Demonstration, in a recent issue of the *American Review of Tuberculosis*, Dr. Donald B. Armstrong, executive officer, refers to a few of the more significant findings which can be briefly stated as follows:

(1) Physical examinations of a large part of the population of this typical American community revealed the presence of active tuberculosis in approximately 1 per cent of the population and another 1 per cent was classified as having arrested tuberculosis. In a city of 100,000 people there are, therefore, probably 1,000 cases of active disease and 1,000 arrested cases.

(2) An intensive search for cases by various means raised the ratio of known cases to deaths from three to one to nine to one. In a city of 100,000 population with 100 deaths a year, or a death rate of 100 per 100,000, there should be about nine hundred to one thousand cases under care or observation. "Does not this indicate," asks Dr. Armstrong, "that the 'next step' in tuberculosis work is the *first step*, namely the dis-

1. Armstrong, D. B.: Four Years of the Framingham Demonstration. *Am. Rev. Tuberc.*, 1921, iv, No. 4, p. 908.

covery of the disease? Is it not of relatively little use to provide adequate machinery for the care of one-third of the active cases in the community if the other two-thirds are undetected and unrestrained or unbenefited by therapeutic control?"

(3) Following a sickness survey carried out by nurses and insurance agents, physicians conducted thorough examinations and discovered approximately nine times as much tuberculosis as was found by the nurses in their search for the disease. It may be concluded, therefore, that adequate medical machinery is indispensable in the detection of tuberculosis.

(4) Routine medical examinations, particularly in schools and factories, will provide excellent opportunity for the discovery of much unrecognized and unknown tuberculosis. The establishment of an expert consultation service is, in the opinion of Dr. Armstrong, the most important single measure developed for the discovery of tuberculosis.

(5) Instead of only 45 per cent of the cases reported by physicians being in an early stage, as was the case at the beginning of the Demonstration, 83 per cent have been found in an early stage with the machinery developed by the Demonstration.

(6) One to two active cases have taken institutional treatment for every annual death in Framingham. For a city of 100,000 and with one hundred deaths annually, there should be available at least one hundred beds for tuberculosis.

(7) The percentage of active cases receiving institutional care was raised from 15 per cent to 33 per cent of the total.

From these Framingham experiences, Dr. Armstrong includes in a complete local program for tuberculosis control, adequate medical machinery, adequate public health nursing machinery, adequate institutional provision, and an effective educational program directed against infection, morbidity, and mortality, proper legislative provision, satisfactory general sanitation, including a hygienic milk supply, and proper organization and coordination of the local health machinery.

It is interesting to note Dr. Armstrong's conclusion regarding the apparent limitations of the effectiveness of this tuberculosis program. Approximately 14 per cent of the cases will escape early detection, and 16 per cent of the active and arrested cases will die in spite of all measures for reducing the mortality. Yet tuberculosis is being brought under control in Framingham. For the decade preceding the Demonstration the corrected tuberculosis mortality was 121.5 per 100,000, for 1920 the rate was 64.5 per 100,000—a reduction of about 57 per cent brought about after four years of intensive work. For the United States

as a whole, this would mean a saving of 75,000 lives annually.

ONE of the last acts of Congress was to curtail the appropriations of the Women's Bureau of the Federal Department of Labor. The appropriation bill passed by Congress limits the salaries of women specialists on the staff of the Women's Bureau to \$1,800. The reduction in salaries of the staff of the Women's Bureau is aggravated further by the refusal of Congress to make even the partial offset of allowing members of the staff the so-called bonus of \$240 a year, granted to other employees.

THE experiment of West Stockbridge, Mass., in proposing to make an appropriation "to induce a doctor to settle in the town," will be watched with interest. The problem implied is a serious one. If there is not to be one more compelling motive to move from the country to the towns, medical and health service must be brought to the country.

THE early deliberations of the conference of the American Medical Association have as their dominant note methods of educating the layman in the interest of preventive medicine, and such modification of professional ethics as will permit the physician to guide authoritatively the lively public interest in health matters.

THE easy way in which people label everything Bolshevistic to which they are opposed frequently becomes comic. Apparently when one has no good argument he falls back on the ever ready boggy of radicalism. One of the most recent of the so-called "radical" measures is the physical education bill in Massachusetts which provides for state aid to stimulate physical education in schools. To apply the term "Bolshevistic" or "paternalistic" to a measure which provides for courses in organized play, sports, and physical exercises in schools is simply ridiculous.

PRESS dispatches state that the maternity bill in Congress was assailed by physicians and declared to be unnecessary. Press reports also recently announced in big headlines that physicians were assailing the proposed prohibition against the prescribing of beer.

The news is misleading. It should be borne in mind that the physicians referred to do not represent the great body of the profession of the country who are unwilling to be stigmatized as the enemies of social progress.

Fatigue Study a Problem in the Home^{*}

The "One Best Way" of Performing Work
Applies to the Home as Well as to the Factory

BY FRANK B. GILBRETH, MEMBER S.I.E., AND L. M. GILBRETH, MEMBER S.I.E., MONTCLAIR, N. J.

THE home presents the most complicated and the most interesting of all modern problems; therefore, fatigue study is more important in the home than anywhere else. Efficient running of the home implies the art of home keeping and the science of housekeeping, and fatigue study affects both.

The home is a plant whose products are happiness and efficient citizenship. It is a restaurant, a dormitory, a school, a hospital, a gymnasium, a playground, and a factory; and in it must be solved all the problems that affect these, as well as its own peculiar problems. Just as in the industries we have gained valuable results by transferring skill and successes from one field to another, by looking for likenesses, and by utilizing the experience of others, so in the home we should look for likenesses to the industries whose work the home parallels, and transfer methods that have proved their success in the industries to this oldest yet newest of industrial fields.

Conserve the Home

Fatigue study has proved its value in the industries. The division of unnecessary from necessary fatigue; the relief of high priced workers by assigning all but their highest priced motions to others; the introduction of rest periods; the emphasis upon the importance of working part of the

time standing and part of the time sitting; the introduction of convenient work places, chairs, and desks, correct posture and right clothing; the realization of the importance of habit,—these have all demonstrated their value in the industries.

It is our task here to show the application of these methods of fatigue study to the home.

Industrial efficiency does not necessarily mean doing away with fatigue, but rather utilizing all available energy. Home efficiency through fatigue study does not aim to eliminate all fatigue. It does eliminate *unnecessary* fatigue. Efficient housekeeping requires the expenditure of much energy. It is probable that the methods of household management can be so much improved that much energy that is now expended in the home can profitably be directed into other channels; but so long as the home exists it must have first claim on sufficient energy to create and maintain its efficiency,—and fatigue study in the home must have as its main product conserving and maintaining the home itself.

The first problem is, then, to determine exactly what are the essentials for an efficient home and to see that sufficient energy to maintain these is forthcoming. The sources of such energy are constantly changing. The human energy available is decreasing through the complications of the labor problem. But the energy available through the machinery and de-

vices at the command of the home keeper is constantly increasing. A large element of unnecessary fatigue in the home today is that caused by failure to use all such available and easily procurable home equipment.

The home has no more right than have the industries to demand of the members of the organization,—which in the case of the home are the inmates,—more energy than can be compensated for with the available rest. If such energy is demanded, or expended, the efficiency of the home must decrease exactly as does the efficiency of the plant in the industries.

Conserve the Workers

Having determined the essentials, or the justified demands of the home, and the amount of energy that must be expended to satisfy these, we have next the assignment of the work. We find a rule that has proved practical in the industries most useful here. The high priced worker should be relieved, as far as possible, from all work except that at which he is most skilled. This means, in the home, that the bread-winner of the family should, as far as possible, be relieved absolutely of home duties, or any participation in the activities of the home, except such as he can do better than can others, or such as will furnish a rest from the activities of the bread-winning occupation. The value of this rule is usually recognized when the bread-winner is a man. Unfortunately, when the breadwinner is a

^{*}Presented before the Society of Industrial Engineers, Milwaukee, Wis., April 27, 1921.

woman, the importance of the same rule is usually underestimated. The wage-earning mother, daughter, or sister who contributes to the family maintenance, has a right to full efficiency for the wage-earning occupation, and should not be expected, except in an emergency, to be a member of the working force within the home. Rest and relaxation, within the home or without, during non-working hours are not only the right of the wage-earning individual, but a factor in the efficiency and best interests of the family, and should be so recognized.

Within the household, also, the more skilled members should be relieved by the less skilled wherever possible, not only as adding to the efficiency of the skilled worker, but as a method of training the unskilled.

Work periods and related rest periods, which have proved so profitable in the industries, can also profitably be used in the home. It is true that the activities of the household are so varied and extend over so many hours, that it is more often possible to arrange a schedule that will permit change of posture, exercise and rest than in the average occupation in the plant. We must remember, however, that change of occupation is not necessarily restful, and is apt to be extremely unpleasant to certain types whose "warming-up period" is long, and concentration strong. We must remember, also that the nervous strain incident to caring for small children, the lack of opportunities for sociability and consequent relaxation; the constant necessity for rearranging and adjusting a program which must be extremely flexible,—these and other factors which may call for consideration in individual homes make a complicated problem. This is not to deprecate in the least the splendid work of individuals and of the home economics departments in the various colleges on the problem of the household. It is to bring before this group of industrial engineers the complexity of the whole problem and the need for the application of the best that engineers, psychologists, and other scientists have to give.

Absolute Rest Essential

A certain amount of absolute rest, not only after the day's work, but during the day's work, is essential. This rest may be most easily and quickly taken reclining absolutely flat, with no pillow. A short rest period, before one is overtired, will do more than a much longer rest period when over-fatigue has actually occurred. Mental rest as well as physical rest

is essential. This latter results far more often than we think from a restful physical attitude.

We turn next to the work place and the rest place. The home should furnish a work place for every member of the household, both adults and children. Though the home is usually rather rest and recreation place than work place for the men of the household, there are individual cases where it is work place for the men as well as for the women, at least part of the time. An efficient work place need not necessarily be large, but it must furnish the essentials for the type of work to be done. Proper heat, ventilation, and lighting,—these are always essential. Equipment either in place or easily available, that there may be the least time expended to "get ready" for work and "clean up" after it; provision for proper posture, and rest and work intervals where the work is to extend over any length of time;—these are the rights of the worker in the household, as in the plant.

The Children Have Rights

In the case of the women of the household, the home usually is the work place for many hours of every day. They have, therefore, the right to demand what the workers in an efficient plant would receive, i. e., an opportunity to produce the most output with the least expenditure of energy, and fatigue. The children, also, have the right,—a not always recognized right,—to an efficient work place both for performing their home activities and for the "home work" that is usually a supplement to the school work. The essentials for their tasks must be considered, and the means for performing them efficiently provided: a work place available and ready, equipment available and ready, quiet, and the incentive or motivation that is a part of successful work.

The rest place must receive the same attention as the work place, and must be ready and available for each member of the household. Perhaps it is not amiss to emphasize the fact here that mental as well as physical rest is needed, and that the book, the magazine or the paper that will interest and at the same time rest, each member of the household, should be as available and ready as is the chair or couch which forms part of the rest equipment.

Provide Rest Equipment

We turn next to a consideration of this chair, which in the industries has received more attention than has any

other fatigue-eliminating device. The efficient work place for long continued operations provides for performing the work part of the time standing and part of the time sitting. This means that the user of this work place is provided with a desk, table or work bench which comes approximately to his elbows when he is standing. He is then provided with a chair which allows him to sit at the same relative height to his work bench or table. This chair should have a foot rest of appropriate height and be on casters that will allow its user to push it into place or push it aside with the least expenditure of effort and time possible. The desk can profitably be cross sectioned, the lines being four inches apart,—to be a constant reminder to study the effects on outputs and fatigue of that great source of free wealth and fatigue elimination. The arrangement of the work upon the work place furnishes another problem, but when the most satisfactory arrangement, for the time being at least, has been found, a drawing of this arrangement upon cross-sectioned paper, corresponding to the cross sections of the work place, will enable the user to maintain this arrangement. If the "One Best Way" of performing the work is kept in mind, as the goal, the improvements will follow naturally and be of permanent value.

Posture is equally important in the home and in the industry. So much has been done by the Posture League on this subject, and their literature and charts can be used to such advantage in the school and in the home, that the practical applications of eliminating fatigue through correct posture are easy. The League studies of posture at work are being supplemented with studies of posture at recreation and posture at rest, and the chair and clothing are receiving equal consideration.

Appropriate Work Clothes

The question of clothing, so important in fatigue study in the industries, is a subject demanding special attention in the home, which is the best field for experiment along these lines, for this reason. The plant serves as social center as well as work place for many members of the community, especially for women. Consequently, it is difficult to insist that clothing appropriate for work be worn during work periods, as it is not practical that this clothing should be changed for what the workers, at least, feel is clothing appropriate for social relaxation during the rest or recreation

periods. In the home, facilities for changing are at hand, and there is no excuse for not wearing appropriate work clothes during work periods, and indulging in satisfying clothing and shoes during the rest, relaxation and recreation periods. "Appropriateness," that test for clothing, may well be supplemented by the phrase "from the fatigue standpoint." During the work period or recreation period, clothing may be appropriate and at the same time leave as its direct product giving pleasure to the wearer, for any fatigue that this clothing causes during the short period of relaxation will be more than compensated for by the satisfaction which results from its wear.

The amount of time consumed and the difficulties of putting on, adjusting, and taking off clothing is an important element in the fatigue produced. Work clothing, especially that which is adjusted and taken off at the plant, must be easily put on and taken off. Fatigue elimination can profitably be held in mind in the design of all clothing. Easily adjusted clothing for the adult is important, but not so important as easily adjusted clothing for the child. Garments that the child can put on and off himself, with the least time and with the least effort, not only mean relieving the older person from unnecessary work, but also training the child to be *dexterous* and finally *skilled* in his motions. This training is a valuable part of the Montessori System and much of this system can be profitably and easily carried out in the home by keeping this thought in mind when clothing is designed and made or bought.

The amount of time necessary to make, to repair, to launder and to keep in shape all kinds of clothing and shoes also requires attention.

Stress Good Habits

Perhaps the most important element of fatigue study in the home has to do with habit. For a long time education, and lately industry, has concerned itself with the question of habit. In the old days bad habits were given the most attention, but in these days it is good habits that are stressed and their usefulness as a tool for efficiency. The home is the natural and most profitable place for habit formation. The child is in the home during the years when it is most easy to form habits and the habit of fatigue elimination, of thinking along the lines of the causes and effects of fatigue, should be started at an early age. Fatigue study is a practical thing. The theory of fatigue and its

causes: the science of measuring fatigue;—these are extremely technical and are, as yet, in the laboratory stage. But the practical application of rules for preventing unnecessary fatigue and for providing for overcoming such fatigue as must necessarily result, is simple and easy.

Fatigue study can be followed in any household where there is a willingness to undertake the work and to look facts in the face. It is not necessary to outline the process here. It is the same as it is in the industries: (1) the survey recording the present conditions; (2) the careful study of the conditions as they exist and the outline of the changes to be installed; (3) the introduction of the new standards; and (4) the most important, the maintenance of new habits after they have been formed. The greatest success, of course, will result where there is the greatest amount of co-operation among the members of the household.

It need scarcely be said to an audience like this, that the presence of an industrial engineer as a member of the household will greatly accelerate progress,—for so much, not only of the theory, but of the practice of better management that has proved successful in the industries may be transferred to the home. Process charts, progress charts, standardization, incentives, learning to think in elements of motion, the theory of tolerance, these and almost countless other methods and devices of management, well known in the industries, should become equally well known in the home. Of course, anyone, and especially perhaps the intelligent homemaker, can study the literature of management and easily transfer from that vocabulary to the home vocabulary. How much easier, however, is it when a member of the household already uses both vocabularies more or less freely, and can not only think the thought through into the new field, but apply it directly. And with such worth while results to the home and to the industry as well! For the home is not only the field *from* which our industrial workers come, but also that *to* which they go. With the proper habits of fatigue elimination in the home, the worker will go to work better prepared to work and utilize the time of rest and recreation.

The Emotional Background

One thing more. There is an emotional factor in behavior as affected by fatigue which has as yet received little study, and which is often under-

estimated or not considered at all. Yet we all know it. It is embodied in a line of Kipling, "They shall work for an age at a sitting and never be tired at all."

We all know that it is possible to work for a long stretch and become extremely fatigued, yet apparently recover because of some emotional stimulus, like praise or some other reward. We all know that it is possible to seem to be working without fatigue, yet suddenly to experience excessive fatigue under a depressing emotional influence.

The home is the great emotional factor in the majority of lives. It is the finest experiment station in the study of the effect of the emotions upon work and fatigue.

Psychologists, psychiatrists, and physicians who are studying these problems have not as yet formulated a definite working practice for either the industry or the home. But we at least know the importance of incentive and motivation, and especially the profitable results of seeing that the reward for success is adequate and prompt.

Where industry is efficient, both reward and punishment are satisfactory, if not always satisfying. The home, however, can not only control its own incentive, but can supplement the plant by seeing that the fatigue eliminating effects of the reward are conserved, and that recovery from the fatigue causing effects of the punishment is assured.

Thus it becomes important here as elsewhere to analyze efficiency, for fatigue study in the home can not only utilize the experience of industry but can assist industry to eliminate waste, conserve energy, and add to the efficiency and happiness of the community.

Responsible for Accidents Caused by Horse Play

Where an employee while devoting his time to his work was struck in the eye by an apple thrown by a fellow servant engaged in horseplay, the injury was held by the courts to be one "arising out of and in the course of his employment," within Workmen's Compensation Law.—*Leonbruno v. Champlain Silk Mills*, N. Y., 128 N. E. 711.

Injury by shooting compressed air in play held not one "arising out of employment within Compensation Act."—*Payne v. Industrial Commission* (Ill., 1921), 129 N. E. 122.

Michigan Mutual Liability Company Service

Here Physical Equipment Is Precisely Adapted and Method Continuously Checked With End Result

By H. N. TORREY, M.D., SURGICAL DIRECTOR, DETROIT, MICH.

THIS statement of the surgical organization and plans of the Michigan Mutual Liability Company is presented to the readers of THE NATION'S HEALTH with the hope that it will contain something of value to others interested in the care of industrial wounded.

The Michigan Mutual Liability Company is a mutual organization of many Michigan employers, whose purpose is to cement the bond which should exist between every employer and employee. It accomplishes this by rendering service in every department, but especially in those departments responsible for the restoration of the employees to industry with the least possible suffering and the least possible delay, all of which demands the utmost in efficiency and results in the wisest economy.

This company maintains its own surgical staff both in the state of

tain points of value. It must be understood at the outset that we care for only the industrial wounded among the employees of company members who are protected under the Michigan Workmen's Compensation Act.

State Organization

We have divided the state into zones, the extent of each zone depending upon the number of company members and employees therein. One surgeon and one ophthalmologist, ranking highest in that community, are appointed as consultants, and are called upon for special examinations and special work among our patients in that locality. Besides the consultants, local field men are appointed, and they handle the routine work, their number and location being especially adapted to the number of company risks in their locality. In most cases the manufacturers select their own field surgeon; our only condition in such a selection is that the surgeon must be competent. Many of the factories of our members are equipped with a first aid room with attendant nurse or first aid man. The following up and correlating of all this work is the duty of a surgical supervisor, and this position is of the highest importance. Over the Supervisor's desk come all reports of acci-

dents, which reports include the diagnosis and treatment of the injury, together with the name of the attending physician. The Supervisor must furnish all possible company cooperation to the attending surgeon in the care of his patient, placing at his disposal the proper equipment, proper hospital facilities, and, above all, the best consultants. The important duty of installation of various first aid stations, the selection of surgeons, the adjusting of complaints, the coordination with the Legal, Claim and Safety Departments, all belong under this head. I might add, that in practically every case, the local profession and local facilities are used in the care of our cases. However, the Company's facilities centralized in Detroit are used where such local facilities are not available.

Detroit Organization

The city is zoned on the same basis as the state. Local surgeons are appointed to handle the routine cases in their vicinity, and their duties consist of caring for the injured employees at the various factories, and the handling of emergency cases in their district. In practically all of the larger factories first aid rooms with a nurse or proper attendant are installed, and many of these stations are equipped with Thomas splints for the trans-

SCHEME OF ORGANIZATION OF SURGICAL SERVICE

Fig. 1. A simple and practical correlation of function which leaves ample freedom to the several departments with no sacrifice of unity in the department.

Michigan and the city of Detroit and owns and operates its own hospital. The organization of the Surgical Service can best be seen by the diagram shown in Figure 1. At first glance this scheme may appear complicated, but under the conditions as we have them—the number of surgeons employed, the close coordination among the various departments, and the large number of patients handled—not only is this plan of organization simple, but it is extremely practical. In the limited space allowed this article it is impossible to discuss this comprehensive organization in detail, but it may be profitable to go over the scheme briefly and bring out cer-

Special planning and equipment have related the whole plant to the industrial surgical field. Stratton & Snyder and Marcus R. Burrows, Associate Architects.

us and solves one of our most perplexing questions, viz., the permanent employment of "the repeater" or the ambulatory patient who is always in our clinic, but who can do light work

Fig. 4. The first floor houses the administrative offices and provides commodious quarters for the Out-Patient Department. The out-patients are handled with expedition and independent of the other departments.

provided he receives any cooperation from that Czar of the factory, the Foreman. We will all concede the ideal occupational therapy shop is the shop where the patient is working. There he has his friends and there is where he is interested. How many times we have sent "John" back with a note to the foreman authorizing him to do light work and the next day or two he reappears in his old haunts with the customary explanation that the foreman said "he wasn't running a hospital." Not only does this patient get into a depressed mental state, but he becomes a trouble maker. What is more to the point, he does not recover function in one-half of the time he would with the proper exercise of the affected part. We have solved this problem by the services of a man whom we have called our "rehabilitation man." This man knows enough of the mechanical game so that the foreman will listen to him, and he also knows something of surgical injuries so the surgeon's instructions can be intelligently carried out. The repeater who can do light work is turned over to the rehabilitation man who goes with him to his foreman explaining the situation to him and obtains his cooperation. Frequent follow-ups at the shop and occasional reporting at the clinic, solve this problem, and both employee and employer reap at least a 50 per cent saving of time and money. In some cases the patient cannot return to his original work, then the rehabilitation man sees that the patient is satisfactorily placed at other work.

In this connection, I would bring to your attention an innovation which has worked out very successfully with

Our social service is chiefly concerned with investigating and remedying home conditions when necessary to the care of patients, besides following

mated and such date is extended or not as the case progresses. Referring to other departments is likewise indicated by initials of same under the proper date.

Out-Patient Department

Owing to the large number and severity of our fracture cases, one floor of the hospital is devoted to their special care. I cannot lay too much stress upon the great importance of having the proper equipment for the handling of these cases. Our results with the various traction methods, utilizing, wherever possible, the Balkan frames, have been especially gratifying. X-ray follow-ups weekly are essential to the proper and intelligent after-care of major fractures. The equipment of our city first aid stations and our ambulance with Thomas splints has done much to cut down the number of compound fractures received.

Another exceedingly important factor in our work is the Safety Department maintained by the Michigan Mutual Liability Company. The Company realizes the enormous value of preventive measures and has made every endeavor to bring this department up to the highest efficiency.

I need not say to one engaged in this work that accurate clinical records are essential. Private case records should be kept, but industrial records *must* be kept. Residents refuse to be clerks and the records suffer. In our organization the difficulty has been solved by supplying a medical secretary, who takes dictation on operative procedures, ward rounds, and clinical records of any descrip-

New Hospital Plans

These plans were drawn with the one idea of handling industrial cases, efficiently, quickly, and economically. Attention is directed to the general

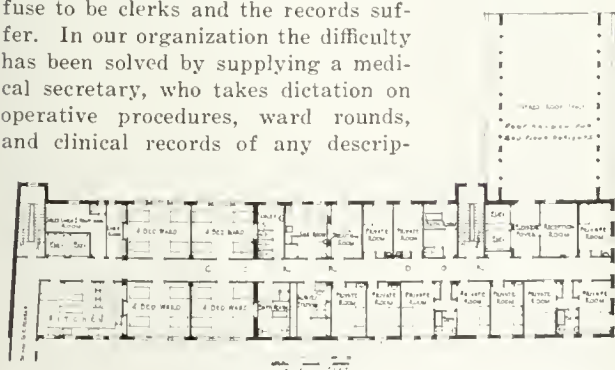

Fig. 5. Fracture injuries, constituting so important a phase of industrial surgery, has been given the entire second floor with such facilities as will reduce the work and assure better end results for all concerned.

Fig. 6. The third and fourth floors are devoted to ambulatory hospital patients, who are separate from the hospital proper, an arrangement greatly to the advantage of the convalescent patients.

scheme, which shows the various units so arranged as to give the closest cooperation between the executive offices, the hospital, and the various departments. This close cooperation between the central offices of the company and the hospital is not only of great importance, but is absolutely essential.

In regard to the Hospital Building proper, it will be six stories and will

Hospital service and passenger service have been separated, the hospital service including its elevators have been placed in the rear of the

by ambulatory and by hospital cases. This, as can readily be seen, obviates the necessity of admittance of ambulatory cases to the hospital proper. In the wards, movable low partitions give the patient privacy, and at the same time do not interfere with economical administration or with ventilation or light. The kitchen, laundry and all the general service functions are housed in a separate

Fig. 7. The operating suite with related departments are housed in juxtaposition on the fifth floor. Too much stress cannot be laid upon the proper equipment and the suitable relation between the units.

Fig. 8. The necessary dining rooms, rest rooms, and open and closed roof space afford easily and without sacrifice of line, the necessary privacy and rest for the personnel of the working staff.

contain one hundred beds. The general scheme is as follows:

Basement.—Storage, vocational shops, etc.

First Floor.—Administration, together with a large out-patient department. The **second floor** will be equipped for fractures and serious cases,—the third and fourth ward floors for ambulatory patients. The **fifth floor** will house the operating room, and the **sixth** the staff and nurses' dining and rest rooms, together with large open and covered

hospital building, and the passenger service in the front. A special effort was made to perfect the Outdoor Department, and to connect it closely with the hospital proper, while at the same time separated enough to eliminate the various objectionable features of too close proximity. All out-patient services, including an operating suite, are distinct from the main hospital, yet at the same time such general departments as the x-ray department and physiotherapy are so located that they may be easily utilized both

building, with free communication by tunnel and bridge between the various buildings.

Naturally in the scope of such a paper as this, it is impossible to go into any great detail. We hope, however, that perhaps others interested may find some points of value. We feel that medical service to the industries is a very important subject, and that more and more will be demanded in the line of better service, and we are doing our best to be ready to meet it.

Secretary's Page

FRANCIS D. PATTERSON, M.D.

In the matter of industrial and dental dispensaries it has heretofore been impossible to compile anything like an adequate list of the firms who maintain industrial dental dispensaries, and an investigation has been undertaken to this end by means of a questionnaire sent out to every member of the American Association of Industrial Physicians and Surgeons. Full cooperation on the part of the membership should result in bringing together data of the greatest value both in the measure of good service and in the interest of extensions of the services maintained as integral parts of medicine in industry. The questionnaire follows:

Industrial Dental Dispensaries

After supplying the information requested by the following questions kindly mail this form to Dr. Francis D. Patterson, Chief, Division of Industrial Hygiene and Engineering,

Third and North Streets, Harrisburg, Pa.

Name of Plant
 Location of Plant—Street
 City State
 Number of Employees in Plant
 Number of Employees Using Dental Dispensary
 Cost of Original Equipment
 Number of Units in Dispensary
 Cost of Dispensary per Year per Patient
 Cost of Dispensary Borne by Company
 Cost of Dispensary Borne by Employees
 Cost of Dispensary Borne by Employer and Employees Together...
 How is Cost Divided?

Steel Workers' Sickness

Statistics of sickness covering one week or more among members of the Sick Benefit Association of a large Pennsylvania steel company for two years ending in July, as compiled by D. K. Brundage, for the United States Public Health Service, show somewhat surprising results. Respiratory disease, such as influenza, grippe, and pneumonia, account for 50 per cent of all cases; bronchitis, pleurisy, and tuberculosis add 11 per cent more; rupture and infection together, 4 per cent, excluding occupational infected wounds; general debility applied to men no longer able to work in the mills, 1.5 per cent. The average age of these men was 68; their employment had lasted an average of forty years. The high incidence of respiratory diseases calls for a more definite application of hygienic air conditioning as well as fatigue and other studies in the steel working trades.

Causes of Work Accidents Among Women

Prevention Implies a Proper Correlation of Causes
Whether the Work or the Worker Is at Fault

BY NELLE SWARTZ, CHIEF, BUREAU OF WOMEN IN INDUSTRY, NEW YORK STATE DEPARTMENT OF LABOR

"WE MUST make the workplace fool-proof," is a time-worn saying of safety engineers. They have learned from experience that accidents occur not when workers are alert and careful, but when attention has wandered, or when fatigue has set in.

Accidents may be due to mechanical, physiological or psychological causes.

Safety engineers generally agree that safety devices can be made to prevent from 25 to 33 per cent of industrial accidents; so that while mechanical appliances play an essential part in accident prevention, it is not the largest part.

Human Factor Variable

In discussing work accidents and their causes, we are too much accustomed to dwell upon the concrete objects of danger, such as unguarded machinery, unlighted halls, and the like. Besides all these external factors and their effects, we must reckon with the human subject himself, and the reason why among so many ever-present chances of danger, so many escape.

The Bureau of Women in Industry of the New York State Department of Labor undertook a study of work accidents among women with the hope that some light could be thrown on the subject of accident prevention among women, to enable the subject to be approached with more understanding. One thousand compensated accident cases for women were studied, through the courtesy of the

Bureau of Compensation, covering the period from June 1, 1917, to June 1, 1918.

There are, of course, certain limitations in a study based on compensation records. For example, a statement as to the time the accident occurred may vary considerably, since there is the testimony of the employer, the employee, and the doctor.

YOUTHFUL WORKERS PAY HIGHEST TOLL OF ACCIDENTS

10% WERE
UNDER 21
YEARS OF AGE

32% WERE
BETWEEN
21 AND 31
YEARS OF AGE

The inordinate penalty paid in accidents by the inexperienced worker but serves to emphasize society's responsibility toward the untrained.

In answer to the question of how the accident happened, the employer often charges carelessness of the operator, and the employee, on the other hand, charges carelessness of the employer. These limitations understood, compensation records have decided merits. Besides the cause of the accident and the kind of injury sustained by the worker, it is possible to follow the development of the injury and to note the disability features.

In consideration of the woman worker, both her mental and her physical characteristics are involved. Inability to understand the English language can easily be seen to be productive of accidents, although inability to speak English was found in a little less than one-tenth of the cases in this study. It is interesting to note that the percentages in and about New York City and upstate were practically the same. The clothing

industry in New York City showed a larger proportion of foreign speaking women workers injured than any other. The textile industry upstate had the next highest percentage. In conclusion, it must be said, however, that for light on the industrial accidents studied by the Bureau, one must look further than to mere lack of word intercourse.

Experience a Factor

Length of service of the worker is an important factor in women's work accidents. Of the accidents studied, 18 per cent of the women had been with their employers less than a month, about 50 per cent less than six months, and about 63 per cent less than a year. This indicates the close relationship between accidents and labor turnover and the value of accident prevention through administration which tends to stabilize the working force.

Lack of training undoubtedly entered into this group of accidents. It is an odd commentary on the efficiency of industry that so little scientific attention has been given to the task of adequately training the worker for her job.

Our responsibility for women's accidents is doubly great, because it is

THE CAUSES OF WORK ACCIDENTS AMONG WOMEN

New York State 1917-1918

Mechanical causes have been traced, but physiological and psychological elements need to be correlated before we can postulate the real underlying causes of accidents.

PERIOD OF SERVICE OF 1000 INJURED WORKING WOMEN

New York State 1917-1918

The degree of protection afforded by the precision and quick reaction time in fully adapted operators is shown by the comparative periods of service of injured workers.

the young woman who pays the highest toll. Almost half of the women were less than 21 years of age, with 60 per cent not more than 25 years of age.

Great emphasis has always been placed on women's clothing as a source of accidents. As a matter of fact, only about 2 per cent of the accidents were traced directly to clothing. In three cases, the hair of the women caught. In two other instances, the hands of the workers were drawn in, because of the gloves worn. High heels worn by women are no doubt a contributing factor toward the number of stumbling and falling accidents, and such accidents ranked second to those caused by machines.

In industry, it makes very little difference if a man is married or not married, but with women marriage is bound to be a complicating factor. Superimposed upon the fatigue from factory work, comes the burden of domestic tasks, much heavier than those of unmarried women. With this in mind, it is significant that 28 per cent of accidents fell to married women, who composed but 10 per cent of the total number. The figures indicate, therefore, that more married women are injured in proportion to the number employed than single women. Fatigue is bound to play an important part where the woman is both the bread winner and the home maker.

Almost 90 per cent of the injured working women were receiving less than fifteen dollars a week. The youth and lack of experience of the workers account in part for the smallness of remuneration, but even in this war period, when wages were at their highest peak, less than 1 per cent received twenty-five dollars or more a week, and more than half were receiving less than ten dollars a week.

Women to the extent of about 10 per cent were not actually at work, in the narrow sense of the word, when their injuries were inflicted. They were going to or from their benches or machines to the dressing room, or to and from their work for the day, along staircases or halls. In studying the source of accidents, the most striking fact that stands out is that the greatest number occurred in connection with machinery. This is due in part to the fact that during the war, large numbers of women for the first time were doing machine work. The metal industries led in the larger proportion of machine accidents, with the astonishing peril of presses. The accident rate among women press operators is considerably higher than

among men, according to a comparatively recent Federal report.

Upon the sewing machine must be placed the responsibility for machine accidents in the clothing industry. This may seem astonishing to the lay mind, which recalls no accident at any time in connection with the sewing machine at home, but the factory power machine, setting about four thousand stitches a minute, is a different thing from the domestic species. With such speed, the operator ceases to see the needle, and a flash of white light takes its place. While needle injuries are not apt to be serious, the danger comes from lack of care and consequent infection.

The machine that stands out prominently in the paper industry is the corner stayer.

The machines that reap the heaviest toll in the textile industry are the loom, the knitting machine, and the draw frame.

Certain Injuries Obscure

From the records, the lifting of heavy burdens caused a smaller number of injuries among the thousand women's accidents than was expected—less than 1 per cent. Physicians claim that accident statistics on this subject cannot be taken too seriously, however, since it is often difficult to trace injuries to this source, and such injuries are very often slow in developing. Employers for the most part have done a great deal to prevent injuries from heavy lifting, by providing pulleys and tackle, but a type of heavy burden that escapes any serious thought is the lifting of piles of finished goods. This type of lifting is common enough, for example, in department stores, and clothing factories. Here no single article is particularly heavy, yet by thoughtless heaping, the weight may become a hazardous element.

Stumbling and falling accidents were second only to machine accidents, forming about 17 per cent of the whole. Why do people stumble and fall? Poor lighting of halls, or bad construction of staircases; obstacles, like piles of goods; or floors wet from spilled hot starch; or even, as in one case, a recently scrubbed floor, which had not been done early enough to allow the water to dry. All these are direct causes; of indirect causes, such as fatigue, we can only guess. Certain it is that we all stumble and fall more when we are tired.

The part of the body hurt, and the type of injury inflicted, indicate something of the degree of severity. Of the parts of the body injured, the

thumbs and fingers seem to be far in the lead.

The majority of thumb and finger injuries came from machines. Of the arm and hand injuries, about one-half came from machines.

Of the leg and foot injuries, one-half came from stumbling or falling.

Of the trunk injuries, practically two-thirds came from stumbling and falling.

Of the head and neck injuries, almost a third came from machines. The rest were scattered in origin.

Almost half of the injuries were cuts, punctures, or lacerations, and most of the disabilities of all types were merely temporary. The time element is a means of indicating the seriousness of the injury. This element, on the whole, was low, but it may be much understated. According to the records, about half of the disabilities were of less than six weeks duration.

Full justice would not be done to a study of this kind without some personal interviews with the women workers themselves. One hundred such interviews were held by the Bureau, and the human story of the industrial accident was told. One-half of the girls pronounced themselves unable to return to work when their compensation period was over. While personal prejudices may have biased the opinions, so large a number would indicate that some had not been able to return to work. Physical disability was not the only thing which kept the injured worker from getting back to work. Some could not find employment, when they were able to work. Changes to different kinds of work were made by some whose accidents had made them afraid to go back to their old jobs. The chief criticism these women made of the New York compensation law as it stands, was the two weeks' waiting period before compensation began. In many instances, this entailed great hardship.

Who Suffers Most?

In the final analysis, who is the woman suffering from work accidents? (1) The one who is young—under twenty-five years of age, who is untrained, unskilled, and at the lowest rung of the wage ladder. Her injuries, so far as is known, are minor injuries, and she receives compensation for a comparatively short time.

But this does not tell the whole story. In a study of accident causation, much more is unknown than known. We have considered for the most part only the concrete causes. The whole physiological and psycho-

logical field remains open for investigation. If we are to reduce considerably the numbers of the maimed and crippled, if we are to eliminate that bugaboo of the workers,—fear; if we are to give some degree of freedom to the human agent apart from the machine, we must consider carefully these causes. Side by side with perfection of mechanism and safety appliances should go the study of those underlying physiological and psycho-

logical factors which so largely contribute to swell the accident rate, and which, when better understood, may be modified, if not obliterated, by the provision of periodic rest periods, reduction of hours for work, change of processes during the day, and similar devices to check the inroads of fatigue.

We cannot get away from the intricacies of modern industrial development; we cannot get away from

the speed of processes or the pace of machines, but we can prevent the never ending cycle of waste before remedy, destruction before attention.

The best guarantee of safety in a plant is a group of careful and alert workers. Carefulness and alertness, like other assets, can be had only at a price.

This price is an absence of fear, and of fatigue, and the recognition of a policy which sets life above dollars.

What Constitutes Industrial Blindness*

By EDWARD STIEREN, M.D., OPHTHALMIC SURGEON, JONES & LAUGHLIN STEEL CO. AND P. & L. E. R. R., CO., PITTSBURGH, PA.

AN OBJECT one centimeter in size, placed one meter distant from a normal emmetropic eye is plainly visible. If this object is moved farther and farther away, it forms a progressively smaller visual angle, until a point is reached beyond which it cannot be perceived, owing to the diminutive size of the visual angle. The limit of perception has now been reached.

The angle which the object subtends at this distance from the eye represents the maximum acuteness of vision. An object twice the size would be seen distinctly at twice this distance. An object one-half the size could not be distinctly seen at more than half this distance.

On this scientific basis Snellen constructed his test-types which are in universal use in recording the acuity of vision. He determined the normal acuteness of vision to be the power of distinguishing letters subtending an angle of 5'. These letters are formed of strokes whose width is one-fifth the size of each letter; consequently they are seen under an angle of only 1'.

Tests of Visual Acuity

In recording the visual acuity of a patient, he should be seated twenty feet from the test-type, which should be well illuminated, and the vision of each eye tested separately by occluding the other eye.

The acuteness of vision is found by determining the smallest type which can be read and the result is recorded by writing down a fraction, the numerator being the distance the patient is seated from the chart and the denominator the line read. Thus, if a person seated twenty feet from

the test-type reads the line that should be read at twenty feet by an emmetropic eye, his visual acuity is recorded 20 over 20 (20/20) or normal. Should he be able only to read the thirty-foot line, the visual acuity is recorded 20 over 30 (20/30). Should the eye be so defective that he can discern only the large letters intended to be read at 200 feet, his visual acuity is recorded 20 over 200 (20/200).

As stated above, this is the method employed by ophthalmologists in all parts of the civilized world. It is an

foot distance, which equals 5 per cent for each loss of ten feet distance. Computed in this manner, it is a simple matter to arrive at the percentage of vision loss, since the standard Snellen test-type are made with each progressively larger line representing ten feet more loss of visual acuity. Normal visual acuity is represented by 20/20, which means that type of the size shown in Figure 2 is plainly visible at a distance of twenty feet. If at this distance type of the size shown in Figure 1 cannot be seen, the vision is represented as 20/220, which

P L R B T A E

Fig. 1. If type of this size can be read at twenty feet by an emmetropic eye, the visual acuity is rated as normal.

international method of recording acuity of vision, simply this and nothing more, and it is to be much regretted that the erroneous idea that these figures when reduced to simple fractions represent loss of vision, obtains in a greater or less degree. That is to say, a few, not having given the matter sufficient thought, will say that a man whose visual acuity is recorded 20/30 has but two-thirds normal vision; 20/40 in their minds can be reduced to ½ and represents only one-half normal visual acuity, etc., etc.

Such conclusions are absolutely wrong and misleading, and I am sure, were Snellen alive today, he would be much chagrined at having his efforts so badly misconstrued.

A table of percentages of vision has been compiled by Dr. V. A. Chapman of Milwaukee, which has been pronounced mathematically correct by expert mathematicians. The principle of this table is to allow ½ per cent loss of vision for each loss of one

is to be interpreted as a total loss of vision.

The table works out as follows:

PERCENTAGE OF VISION LOSS	
Vision of	% Loss of Vision
20/20	0
20/30	5
20/40	10
20/50	15
20/60	20
20/70	25
20/80	30
20/90	35
20/100	40
20/110	45
20/120	50
20/130	55
20/140	60
20/150	65
20/160	70
20/170	75
20/180	80
20/190	85
20/200	90
20/210	95
20/220	100

We have in this table a percentage of visual losses ranging from normal vision, which for decades has been established at 20/20, to vision of 20/200, or industrial blindness.

By the latter is meant that an eye which is incapable of reading the 220-foot line at 20 feet is blind in the

*Read before the Twelfth Conference of Industrial Physicians and Surgeons of Pennsylvania, Pittsburgh, April 15, 1921.

sense that it is not fit to do any kind of work. This is not total blindness—which implies the absence of light perception—and the possessor of such poor vision can still see enough to be able to get about.

In an industrial sense, compensation is payment for the economic loss to a person in consequence of damages to the functions of any part of the body from injury.

There may be no loss at all following an industrial accident, the injured member recovering its function completely; or there may be partial

compensation Act in Pennsylvania, for the loss of an eye or loss of working vision in an eye, a maximum of twelve dollars per week for one hundred and twenty-five weeks is allowed. It would seem a most equitable adjustment to apply the above percentage table in all cases of partial loss of vision and award damages accordingly.

Compensation for Visual Loss

For instance, vision by an industrial accident has been reduced to 20/100; the claimant would therefore

further, counsel for the Minimum Wage Board of the District of Columbia, and Mary W. Dewson, research secretary of the National Consumers' League. This volume sums up the argument for the Minimum Wage Board of the District of Columbia under four points:

(1) The presumption to be accorded an Act of Congress, which demands that it be respected unless transgression of the Constitution is shown "beyond a rational doubt," amply sustains the District of Columbia Minimum Wage Law, particularly in view of the circumstances of its enactment.

(2) Congress, by this legislation, aimed at "ends" that are "legitimate and within the scope of the Constitution."

(3) The "means" selected by Congress are "appropriate and plainly adapted" to accomplish these "ends."

(4) No right of the plaintiff's secured under the Constitution "prohibits" the use of these appropriate means so adopted by Congress to accomplish these legitimate ends.

In addition to the points of argument, material is presented on the successful working of Minimum Wage Laws, the extension of Minimum Wage Legislation and the need for Minimum Wage Legislation in the United States. This last section includes particularly valuable material on the wages of women and the cost of living.

Industrial Dental Clinics Organized

In a way, industrial dental clinics offer a more promising field for the securing of clinical facts and figures than can be secured by hospitals or dispensaries because as a rule patients are under observation for a longer period of time. Most of the corporations starting dental clinics have already reorganized medical departments which can and do cooperate with the dental work. Records kept should include both dental and medical findings. The purpose and scope of the dental clinic should be primarily educational work among employees; preventive dentistry rather than reparative work; prophylactic treatments, examinations, and x-rays, which properly belong to the preventive and educational branches. Employees should go to outside dentists for reparative work of all kinds, according to a paper read by Thaddeus P. Hyatt before the National Dental Association in Boston. The clinic acts as a time and money saver to the dentist. An industrial medical department is incomplete without a dental clinic.

Fig. 2. The inability to see type of this size at a distance of twenty feet constitutes industrial blindness. This letter is normally visible at a distance of 220 feet.

loss of function and incomplete recovery; or there may be total loss of function. Partial loss occurs somewhere between no loss at all and a total loss of function.

Under the present Workmen's Com-

receive compensation based on 40 per cent of the amount recoverable had he lost the eye, or industrial use of the eye, namely 40 per cent of \$12.00, or \$4.80 per week for 124 weeks, or \$600.

Minimum Wage Laws in Court

THE minimum wage law of the state of Wisconsin has been upheld as constitutional as a result of a test case brought against the Industrial Commission of Wisconsin by one of the leading hotels.

The case for constitutionality of the Minimum Wage Law of the District of Columbia is now pending. The case against this Minimum Wage Commission was brought because of

the order of the Commission providing that, subject to certain qualifications, "no person . . . or corporation shall employ a woman . . . in any hotel . . . or in any hospital at a rate of wages of less than 34½ cents an hour, \$16.50 per week, or \$71.50 per month."

The most significant material on wages published for some time is the brief of some 500 pages on Minimum Wage Laws prepared by Felix Frank-

California Labor Camp Code

IN ORDER to advise owners and operators of labor camps of the requirements fixed by the Labor Camp Sanitation Act, and the Commission of Immigration and Housing in the application of that Act, a bulletin of information has been issued setting forth the minimum requirements which must be provided:

(1) Camps should be located on well-drained ground.

(2) An adequate supply of pure drinking water must be provided. (Statutes 1915.) Barrels or tanks containing water should be cleaned out at frequent intervals. Water should be drawn from barrels or tanks by a faucet. Whenever possible, drinking fountains should be installed.

(3) Sleeping quarters (tents or houses) should be arranged in rows with adequate spaces between.

(4) Toilets should be at least 75 feet from sleeping quarters. The openings of the toilet structures must be either battened or screened and the structure made as fly-proof as possible by automatic drop-seat covers. Lime or ashes should be sprinkled in the pit every day.

(5) Toilet must not be located over streams or canals.

(6) Wherever possible, stables and corrals should be located at least six hundred feet from the living quarters. The direction of the prevailing winds should be considered when the location for corrals and stables is chosen. Manure should be disposed of daily either by hauling it into the field and spreading it in thin layers on the land, or by placing it in flyproof composting pits, or by burning.

(7) Bunkhouses, tents or other sleeping quarters must be provided. Sleeping quarters should have between four and five hundred cubic feet of air space for each occupant. Sleeping quarters (houses or tents) must be in good structural condition. Tents or houses which are in bad repair can not be used as sleeping quarters. Whenever practicable, sleeping quarters should be screened so as to keep out mosquitoes and flies.

(8) Whenever a camp is located on damp ground or when a camp operates in winter, floors must be provided in tents or houses used as sleeping quarters.

(9) Bunks or beds must be furnished to all employees. The bunks or beds must be of steel, canvas or other sanitary material. They must be so constructed as to afford reasonable comfort to the occupants. Where straw is used, a container or tick should be provided.

(10) Tents or houses used as cooking or dining quarters must have all openings screened and doors should have spring hinges to close automatically.

(11) All drainage from kitchen sink must be run through a covered drain to a covered cesspool or septic tank or otherwise disposed of in such

a way as not to become offensive or insanitary.

(12) Garbage and refuse must be kept in fly-proof, covered containers and disposed of at intervals by incineration or by burying or by feeding to hogs. Hogs should not be allowed to roam at large in camp. They should be kept in pens at least 200 yards from living quarters (wherever location will permit). The direction of the prevailing winds should be considered when the location for hog pens is chosen.

(13) There must be an adequate number of toilets, affording one seat for every fifteen persons. There must be separate toilets for men and women, marked "Men," "Women."

(14) In all ranches (hop, fruit or berry), where people work in the fields throughout the day, there should be a few portable toilets. The openings of the toilet structures must be either battened or screened and the structure made as fly-proof as possible by automatic drop-seat covers. Lime or ashes should be sprinkled in the pit every day.

(15) Bathing facilities must be provided at all camps. The use of showers is advised, as they are more sanitary and also cheaper to construct and will accommodate more people. One shower head for every fifteen people should be provided.

(16) Interior of dining and sleeping quarters, bathrooms and toilets

must be kept in a clean and sanitary manner. The grounds around the camp must be kept free from filth and accumulation of rubbish, etc.

(17) At every camp the owner, superintendent or overseer, shall appoint a responsible person to assist in keeping the camp clean.

(18) Section 6 of the act regulating sanitation and ventilation in labor camps reads:

"It shall be the duty of any person, firm or corporation or agent or officer of a firm or corporation employing persons to work in or at camps to which the provisions of this act apply and the superintendents or overseer in charge of this work in or at such camps to carry out the provisions of this act. At every such camp such owner, superintendent, or overseer shall appoint a responsible person to assist in keeping the camp clean."

(19) Section 8 of the act regulating sanitation and ventilation in labor camps reads:

"Any person, firm, corporation, agent, or officer of a firm or corporation, or any superintendent or overseer in charge of the work in or at any camp coming under the provisions of this act, who shall violate or fail to comply with the provisions of this act is guilty of a misdemeanor, and shall upon conviction thereof, be punished by a fine of not more than two hundred dollars, or by imprisonment of not more than sixty days, or by both such fine and imprisonment." (Statutes of 1913, page 328; amended 1915, page 497 and 1919, page 244.)

Committee Studies the Health of Working Children

Owen R. Lovejoy, the general secretary of the National Child Labor Committee, announces in the forthcoming issue of the *American Child* the beginning of a novel and extensive study of the health of working children. This study is being made in the continuation schools of Newark, N. J., with the cooperation of the Department of Medical School Inspection.

Twelve hundred boys and girls employed in the various industries of the city and attending the continuation schools several hours a week will be examined by a corps of doctors and nurses under the direction of Dr. H. H. Mitchell, health specialist of the National Committee. Their physical condition will be compared with what it was when they received their working papers. A correlation will be made between the occupations in which the children engage and their health records while at work.

The object of the study, according to Dr. Mitchell, is to obtain reliable scientific data on which to base conclusions regarding the need of some form of health protection and service

for boys and girls who have left the regular schools and gone to work, as well as to throw additional light on the question of whether the minimum age for entering industrial employment should be raised from fourteen, which is the age established by law in most of the states, to sixteen, which was recommended by the Children's Bureau Conference on Child Welfare Standards in 1919.

"The vast majority of juvenile workers in industry," says Dr. Mitchell, "are between fourteen and sixteen years of age. This, generally speaking, is the period of early adolescence, a critical period from both the physiological and the psychological standpoint. Only seventeen states now require the physical examination of applicants for working papers, and no state sees that working children are periodically examined to learn what effect their employment is having on their health or to afford opportunity for the correction of defects or dangerous tendencies."

The need for a scientific approach from the standpoint of the physical effects of industrial life upon children is a fair and just challenge which cannot be ignored in our welfare programs.

Training at St. John's Military Academy

Resiliency of Physique Finds Its
Counterpart in Mental and Moral Fiber

BY MAJOR ROY F. FARRAND, COMMANDANT, THE ST. JOHN'S MILITARY ACADEMY, DELAFIELD, WIS.

FOR more than a quarter of a century before the war there were here and there about this great land of ours, voices crying in the wilderness to the effect that the ideal training for American youth was military training; that it would make for the physical well being of the race, that it would promote mental alertness; that it would permeate the fiber of our complex American life with a certain virility; that it would give our young males that *savoir-faire* which insures the ability to live a man's life among men; and that, while endowing them with the qualifications, mental and physical, for making a success among the pursuits of peace, it would at the same time be building for the Nation a reserve of man-power of officer fiber, which in the event of war might be called upon to play equally well its part in the grim business of war.

One Man Acts

In the sleepy little village of Delafield, Wis., some thirty-seven years ago, such a prophet raised his voice, but, unlike the prophets of old, he was a man of deeds, as well as of words. He not only cried aloud to all and sundry of the great benefit of military training to our youth, but he set about proving the truth of his own theorizing. Amid the quiet, pastoral scenes of that little Wisconsin village, he breathed the breath of life into an institution which was destined at a later date to merit the thanks of a Nation, though in founding St. John's Military Academy, it is doubtful if Sidney T. Smythe more than vaguely

dreamed of the contribution he was making to the winning of the greatest war of history.

For many years before the war St. John's was recognized as one of the leading preparatory schools for boys in the land. Its students came from all the states, from Canada, from Mexico, and from distant India, China, and South America, while its graduates were building bridges in Africa, manufacturing shoes in Oshkosh, chasing Ladrones in the Philippines, practicing law in Kokomo, farming in Oklahoma, or otherwise contributing to the world's industry and the world's progress. They were

proving the soundness of their mentor's theories as applied to the pursuits of peace.

Then came the war. Then came the final proof of the soundness of St. John's training. By hundreds, its alumni flocked to the colors. Something more than 20 per cent of the male graduates, of a neighboring university, entered the service—nearer 70 per cent of the alumni of St. John's were carried on the rolls of their Country's fighting regiments. Over 50 per cent were commissioned officers, the balance for the most part being barred because of their youth.

For the most part, these men were

The east front of the Quadrangle of St. John's Military Academy. Built in militant English Gothic style, the environmental stimulus is appropriate to the mental and physical disciplinary régime of the cadets.

At bayonet practice, "Long Point."

Learning to throw the deadly hand grenade.

volunteers. They did not wait for the draft. They had not been trained to wait. They had been trained to *do*, and how much America owes to them for the training of the first levies of its great draft army, none but the organizers of those first training camps will ever know. With hundreds of thousands of unequipped, untrained and awkward recruits bearing down upon them, their cry was "Where will we get the trained and intelligent drillmasters to *teach* these men"? And in every camp the graduates of St. John's made answer: "We can do the work—take us." In one great National Guard encampment, a St. John's cadet, eighteen years of age and not yet graduated, was brevetted a Lieutenant Colonel, and made senior instructor in close order drill.

Thus has St. John's justified its existence. Thus has it proved the soundness of its founder's theories, and the clearness of his vision. And today, with the war over, and our citizens again falling into the lethargy of unpreparedness, and listening to the siren voice of pacifism and disarmament, St. John's is quietly and busily

going about the training of more useful citizens, every one of whom is a potential soldier.

It is an inspiration to the average citizen to visit St. John's. It is a beautiful plant, crowning the hill above its clustering village, like some feudal castle of old, with towers and battlements and vine-clad walls. One turns into the grounds through the Argonne Gate, "In memory of these gallant lads of 'OURS' who fought in Argonne Wood," as the bronze tablet by the gateway announces, and immediately one finds himself in the center of the school's activities. He is standing in the main quadrangle around which are grouped the main barracks and administration building, the gymnasium, a recitation hall, and the chapel, all modern stone buildings, built in the militant English-Gothic style. It may be that our visitor will find the quadrangle deserted, but it is no sign of inactivity. He has but to step into the neighboring recitation hall to find a bee-hive of industry. The thirty highly paid instructors who guide the scholastic work of the cadets, do not lose sight of the fact

that a youth's first duty is to get up his lessons, and one only needs to visit these classes to understand why the scholastic standing of the school is so high.

Youth Learns Control

Or it may be that our visitor steps into the quadrangle just as the trim bugler in front of the main entrance is sounding Drill Call. From Norfolk Hall, one block to the west, to Raleigh Hall, the same distance in the opposite direction, the call is caught up and repeated, and then what a scene of life and action ensues. From every doorway, from the east and west and the north and the south, come bronze-faced, lithe, and well set-up lads, each armed and equipped with the latest regulation equipment, and each hurrying to join the long lines of gray-clad figures that are rapidly forming along the gravel esplanade in front of the flagstaff. Suddenly the bugle barks the Assembly; the ranks freeze to rigid attention; six cadet top-sergeants snap out "Report" and there before us, in six well-sized companies, we see the

Shelter tent camp under inspection by officers of the general staff.

Poise and potential leadership develop along with muscles of steel.

"Come and get it." At the call of the bugle, these boys follow all the precise routine of a military post.

Building a military bridge—a matter of about six minutes. Alert, erect, supple, quick with response in collective effort.

five hundred erect, clear eyed, steady young soldiers, who, with their predecessors, have earned the right to be called one of the most soldierly organizations in the world. We see more than that. We see the spirit of American Youth in training. We see the embodiment of youthful earnestness and dignity. We see youthful poise and self possession. We see potential leadership and potential leaders, and if we be of those Americans who *think* we unconsciously straighten our shoulders, and thank God that we have schools like St. John's.

It would take long to tell of all the activities of the cadet's life at St. John's; how, from reveille in the early hours of the morning till taps at night, he follows, at the beck and call of the bugle, the busy routine of a military post; how, carefully dovetailed into and coordinated with this routine, he gets a scholastic training unsurpassed by any school; how, by means of special training in military calisthenics and disciplinary exercises under War Department experts, he is made erect, alert, and supple; and how by means of required athletics, he is given a physique that is fit for any hardship with muscles of steel and the constitution of a backwoodsman.

Health Record Unusual

As might be supposed from the above statement, the health record of the school is unusual. During ordinary periods the daily sick report shows less than one-half of one per cent of the student body "off duty," and that percentage includes the strains and sprains incident to major athletics. During periods of contagion, the percentage will occasionally range as high as 2½ per cent on the average. the great influenza

epidemic of the fall of 1918 was a severe test, but St. John's was one of the few boarding schools in the land which was not compelled to close its doors and it is a noteworthy fact that of the fifty-two cases recorded during the epidemic, all but six were boys who had entered the school for the first time, only a month earlier.

No description of St. John's would be complete without reference to the moral influences of the school. General Leonard Wood has said that no man was ever really a success unless he had a religion, and the lads of St. John's are surrounded with the influence of a religion which would appeal to a Leonard Wood or a Theodore Roosevelt. It is free from cant and dogma, but it bears heavily on the cultivation of the manly virtues. It teaches fair-play, chivalry toward women, contempt for what is low and base, and a reverence for the things of the spirit.

Can one question the value of such training to the youth of today and of the future? With the example of the war before us, with the knowledge of the terrible physical unfitness of our man-power when that war came, and with the knowledge of the growing

indifference of our people to the lesson which that *should* have taught us, it is at least a satisfaction to know that schools like St. John's are standing in the breach, and it is perhaps not too much to hope that they may some day prove to be that "little leaven which shall leaven the whole lump," and when we look about us and see the stoop-shouldered, hollow-chested, pasty-faced, blasé young devotees of the cabaret and the pool-hall with which our city streets are filled, let us remember the full-chested, virile, eager and purposeful young *doers* of St. John's, and take heart again.

Open Nurses' Training Schools

Due to the increasing demand for nurses in the government hospitals the United States Public Health Service has opened two training schools for nurses in its hospitals. One will be inaugurated at Fox Hills, L. I., be- of its nearness to New York and the other will be located at Fort McHenry near Baltimore. Plans are under consideration for the opening of other nurses' schools as conditions permit in such other hospitals as may be fitted for the work.

What Breathing Exercises Accomplish

BY OSWALD HOLMBERG, CAPTAIN IN THE SWEDISH ARMY AND PHYSICAL DIRECTOR OF CHRISTIANSBAD HIGH SCHOOL, CHRISTIANSBAD, SWEDEN

BREATHING exercises are probably more employed than any other form of exercises, both during the obligatory lessons at school and during voluntary gymnastics. They rarely fail to appear among the exercises for the physically broken down men recommended in papers and magazines devoted to health culture. It is easy to surmise that the frequent use of breathing exercises is due to the knowledge that oxygen is indispensable to life.

Which kind of breathing exercises are then used? Mainly deep inhalations and exhalations, executed by leaning the head back, expanding the chest, at the same time automatically drawing in the stomach, making audible the taking in and expelling of the air through the nostrils.

I presume the object of those exercises is to admit more oxygen and segregate more carbonic acid, thus stimulating general health and vitality. But as to the admission of an excessive amount of oxygen scientific experiments have proved that during these exercises the vital capacity is reduced. Even if this were not so, it is not advisable to furnish your lungs with more oxygen than they require and, as to the segregation of carbonic acid, there ought not to be an appreciable reduction thereof in the blood. It is the presence of carbonic acid in the blood that keeps the breathing machinery going. If by strong and persistent breathing exercises the blood is relieved of too much carbonic acid, the subject becomes dizzy and the heart begins to flutter, which has been an experience common to not a few people.

The breathing centrum located in the medulla oblongata, which is minutely adjusted gives us a natural ability to absorb the correct amount of oxygen at the inhalation and give out the corresponding amount of carbonic acid at the exhalation required by our systems. It is obviously wrong to interfere with nature in this respect under the supposition that we take too little oxygen and give out too little carbonic acid; but, somebody may suggest, is it not advisable to stimulate the breathing after a violent physical exercise? No, it is not. Shortness of breath is caused not through lack of oxygen, but through overworking the heart.

The faults with the breathing exercises as practiced in this country are: (1) Executed in a uniform way, and at command interferes with the person's individual form and rhythm of breathing. (2) Breathing exercises may, when executed with excessive chest expansion, as is very often the case, predispose to pulmonary emphysema and tend to affect a sensitive heart, since breathing and circulation are closely related. (3) Breathing exercises, finally, interfere not only with the mechanical part of respiration, but also with the chemical exchange.

What we may accomplish from a

gymnastic standpoint in order to aid the breathing is to develop the mobility of the chest—through bendings, twistings, heave movements—and the anterior abdominal region. The best breathing exercise is running outdoors, when the mechanical part of the breathing gets stimulated in a natural manner in connection with the exercise of the heart and without interfering with the chemical part. As regards shortness of breath, this is not to be made a direct objective nor forced. It should be left to Nature to remedy, but not in a standing or reclining position, but through ordinary marching.

Sanitary Analysis of Milk

THE American Public Health Association has recently brought out the third edition of a report of the Committee on Standard Methods for the Examination of Milk. A summary of the more important changes from the second edition follows:

(1) The scope of the report has been broadened to cover the sediment test and the examination of milk for the presence of long chain streptococci.

(2) A summary of required procedures is given at the end of the report.

(3) Encouragement is given for further investigation of promising new laboratory methods.

(4) Official recognition is given to microscopic counts made directly from unpasteurized milk.

(5) Methods for determining the H-ion concentration of agar media are given.

(6) It is recommended that the practice of speaking of agar plate counts as showing the "number of bacteria per cc.," be discontinued and the words "number of colonies" used.

(7) It is insisted that punitive actions should be based upon the average results from a series of samples, and that, where possible, the routine counts should be verified by suitable procedures when actions based on their use are likely to be questioned.

The present third edition report has been prepared by a committee consisting of W. H. Park, chairman; M. P. Ravenel, R. S. Breed, J. A. Anderson and H. A. Harding, with B. H. Stone and W. R. Stokes as adjunct members. This committee has sought and obtained the cooperation of still

other associations interested in the sanitary control of milk in an effort to make the report truly representative of American laboratory workers.

The first edition of the Standard Methods for Milk Examination was prepared and issued in 1910. A second edition of this report was prepared in 1916 by a committee which worked in cooperation with committees from the Society of American Bacteriologists and the American Dairy Science Association.

Boys' Health is Biggest Asset

"Just because our war with Germany is over, the United States cannot be assured it will not be dragged into another conflict. It will be almost a miracle if we escape some of the difficulties which exist in the world today." This warning was given by Maj. Gen. George Bell, Jr., at a luncheon of the Chicago Association of Commerce. "In view of this outlook," he continued, "it behooves us as a forehanded nation to take such steps as we can in the way of military preparedness, and the backbone of preparedness is better health. It behooves us to see that our boys and young men are given such training that they will be ready when the time comes. Physical fitness is the real index of a nation's military strength. Health records are equally important with scholastic ratings and physical training should be carried on all our curricula."

"Hold on to Health" The Camp Fire Slogan

New Values Are Set Upon Individual Effort to Conform to Standards Necessary for Group Approval

By ROWE WRIGHT, DIRECTOR, CAMP FIRE GIRLS, NEW YORK CITY

IT IS no longer the thing to enjoy poor health. One hundred thirty thousand Camp Fire Girls, organized in every state and in seventeen foreign countries, are making the sickly, hothouse flower sort of girl unpopular. The story of how these girls have made health popular, how they "hold on to health," is an interesting one. It is the story of a program which has made the out-of-doors so attractive that it can hold its own against the movie and crowded dance hall. The Camp Fire Girl considers her health a sacred thing. When she enters Camp Fire and learns the law, which is:

Seek beauty,
Give service,
Pursue knowledge,
Be trustworthy,
Hold on to health,
Glorify work,
Be happy.

she is impressed with the fact that one of her first duties is to hold on to health. Every Camp Fire Girl wants to be strong and well so that she can enjoy life both now and in the future. She therefore sets about to acquire certain simple habits which are important to health. She must learn to sleep enough, to eat the right sort of food, to keep clean outside and inside, not only once in a while, but all the time—and she must take enough and the right sort of exercise.

In order to help her to form the habits of health, the Camp Fire Girl keeps her daily health record. Each

night she checks up on her health chart the things she has done which will tend toward making her strong and well. At the end of the month, she counts up the number of points she has won, and if she has a 90 per cent record she is entitled to wear a health symbol on the sleeve of her blouse. Each additional month that she wins the health symbol she may add a bar to it. The symbol itself means sleep, cleanliness, and exercise. Whenever you see girls with this little emblem on their sleeves you may know that they are a part of the little army of girls who are determined to have healthy bodies.

The biggest thing which the Camp Fire Girls do toward the making of the next generation a generation of healthy women, is in the stimulation of outdoor life. Just as the fire is a center of the home so is the Camp Fire the center and symbol for out-of-door life, and this idea is incorporated in the name of the Camp Fire Girls. There is no Camp Fire Girl who has not learned to love the pleasure of picnicking or tramping over the hills or along the open road or of sleeping under the stars. One hundred thousand Camp Fire Girls went camping last year for one or two weeks and they came back healthier and happier. Camping is considered of such importance in the training of the adolescent girl that on the application blank of each prospective Guardian of a group of Camp Fire Girls

appears the question: Can you go camping with your girls for a week or more? No girl or guardian can spend a week or more in camp without having gained a new and helpful type of experience, for in camp all the daily processes of life are simplified. She returns from a well regulated camp refreshed in body and mind, but, more important, with a new confidence in herself and in her abilities.

Camping does not mean to any girl the throwing off of all restraint, a breaking down of daily routine in order to see how much hardship she can stand. It means exactly the opposite. Every camp which results in mental, moral, and physical gains for the girl must be conducted on a fairly rigid routine. This routine is necessarily different from that of the home. It prescribes regular hours for sleep, exercise, food, and rest, a regulation which is as important to the growing girl when she is on her vacation as when she is at her home. A typical Camp Fire schedule is based on the principle of "Early to bed, early to rise" as well as on the principle of "All play and no work." The following is a typical daily program:

6:45	Getting up.
7:00	Setting-up exercises.
7:15	Morning dip or shower.
7:45	Breakfast.
8:30	Clean up and preparation for tent inspection.
9:00	Tent inspection and singing.

The Camp Fire Girls know how to take care of themselves in the open, even to the extent of pitching their own tents.

Order and precision characterize all the camp arrangements for comfort.

- 9:30. Period for hand craft work or special classes in first aid, etc.
- 11:00 Period for folk dancing, group games, etc.
- 12:30 Dinner.
- 1:00 Rest hour (absolute quiet).
- 2:00 Quiet hour, reading, study, or writing.
- 3:00 Swimming.
- 4:30 Walking, canoeing, riding.
- 6:00 Supper.
- 7:00 Evening stunts and entertainment.
- 9:00 Lights out.

There are certain requirements regarding the health of campers which every director of a Camp Fire Girls' camp is urged to consider. Every girl who is planning to go camping should have a physician's word that she is in good physical condition, that is, that she has no tendency toward any disease which might be developed in camp. The director should be told if any girl is not strong enough to follow the camp schedule.

Preliminaries Necessary

The director of a Camp Fire camp has considerable work to do in the proper purchasing of supplies long before the time for camping. She must have ordered the amount of staple supplies necessary and the brands which she knows to be unadulterated. The dietitian of any camp has a real problem, for she must not only consider the well-balanced meal but the type of food which can be cooked out of doors and over an open fire. No Camp Fire Girl is satisfied unless the majority of her meals while on a camping trip are cooked out of doors. In the "Camp Fire Girls' Manual" and in their "Vacation Book" these are typical menus of well-balanced, suitable meals for campers. These have been not only endorsed by a physician, but have been tested as to their practicability for out of door cooking and for their

ability to appease the appetites of husky campers. There is hardly a Camp Fire Girls' camp in the United States which does not set down as one of its first rules that no candy shall be admitted in camp. Parents are discouraged from sending candy or sweets to their daughters, and the cases of illness in camp are exceedingly few. In the large camps where a trained nurse is in attendance in case of illness, it has been found that her only duties have been to teach first aid and simple nursing.

The camp director should always make sure that the water of the camp is pure. If a new site is being selected, the water should be analyzed and pronounced pure before the selection is made. In camp, whether large or small, there are certain principles of sanitation which are scrupulously followed. The first should be the disposal of refuse. All Camp Fire Girls know that all refuse should be covered, that the refuse hole must be some distance from the kitchen and

that a disinfectant powder like chloride of lime, should be scattered over the hole at frequent intervals. The second principle is the destroying of everyday litter and the refuse which is burnable. The third and most important principle is the building of the latrine. Camp Fire Girls are urged, whenever it is possible, to provide their camp with a chemical latrine. Where this expense cannot be met, the following directions are given: The latrine should never be located on a slope higher than the camp or water supply even though it be some distance away. The hole should be deep and a box of sand or ashes scattered in it frequently. Disinfectant should be used several times a week. The fifth principle is the proper protection of food against mice, squirrels, etc. Camp Fire Girls realize that food is not wholesome which has been exposed to the flies or which has been molested by mice or squirrels. The last principle is a provision for personal cleanliness. Every

Camp Fire Girls out for an over night hike.

The Camp Fire Girls learn folk dancing out of doors. Supple bodies, hard muscles, perfect poise, make possible full freedom of expression.

Mountain climbing and the exhilaration of a night under the stars stimulate the creative imagination of these girls. Repeated excursions of this kind are health giving as well.

Wholesome interests as well as physical education are involved in the garden programs of the Camp Fire Girls.

Camp Fire Girl knows that it is of paramount importance to be clean while she is in camp. She is expected to take a morning dip or shower before she dresses, and is expected to take the same care of her teeth, hands, and hair as she would at home.

Rigid Personal Care

All this sounds formidable to those of us to whom it is new. To the Camp Fire Girl, however, it is not difficult to consider all the matters of health and hygiene when she is camping, because she has become accustomed to taking proper care of herself every day of the year.

All Camp Fire Girls love to go to camp. Most of them earn by group

effort the money for their camping expenses. Some of their camps are most primitive and crude; others are permanent and with adequate equipment, but always a Camp Fire Girl returns from her camping experiences having learned new lessons in democracy as well as in health. For at camp it is the girl herself that counts. She knows she cannot be popular no matter how wealthy her father or how distinguished her lineage if she cannot do the things the other girls can do. She must know how to cook, she must be willing to do her share of the cleaning up, she must be able to swim, and to hike as the other girls do. She must not be afraid of the dark or the noises of the woods at night; she must

be a good sport on the overnight hike and not complain if the ground gets hard or it begins to rain and she has to crawl inside her poncho.

In camp as in no other place in the world, the girl has only her own two feet to stand on. She has to prove herself to be what she pretends to be. The experience of camping with one's chosen friends, of having to share the few conveniences of the camp with several others, of getting the inspiration of the woods and the stars and of all growing things, is one which puts its mark upon the girl and makes her more sturdy of fibre and more understanding of soul.

Federal Housing Division Planned

Senator Calder of New York and Representative Tinkham of Massachusetts have introduced a bill proposing a Division of Housing, approved by President Harding and sponsored by Secretary of Commerce Herbert A. Hoover. It is the revision of the measure originally introduced by Mr. Tinkham July 8, 1919, and proposes to put the new division in the Bureau of Standards under the administration of the Secretary of Commerce, and to turn over to it all the construction and housing data collected by the United States Housing Corporation, the Emergency Fleet Corporation, and the special commission on housing headed by Senator Calder, which last year made a tour of industrial centers, securing first-hand information as to housing needs.

Eyesight Conservation Council Organized

The Eyesight Conservation Council of America which was recently organized has headquarters in New York City. Mr. L. W. Wallace, New York, is president of the organization, and Dr. Cassius D. Wescott, Chicago, is vice-president. The object of the Council is the conservation and improvement of vision through the arousing of public interest in eye hygiene, especially as it pertains to the protection of the eyes in hazardous occupations. The plans of the council include sending out information concerning optics; on the proper lighting of homes, schools, offices, factories, and private and public buildings; trying to promote periodical examinations of the eyes, especially of school children and industrial workers, etc. A nation wide "Save your sight" campaign will be conducted by the organization.

Group exercises stimulate competition, and the value of the setting-up exercises indulged in each morning is fully apparent.

Infectious Diseases in Summer Camps

Forethought Is Better than Afterthought; Prevention Better than Cure

By D. L. RICHARDSON, M.D., SUPERINTENDENT, PROVIDENCE CITY HOSPITAL, PROVIDENCE, R. I.

THE popularity of summer camps for boys and girls is generally recognized and they are increasing in numbers every year in all parts of the country.

No one will dispute that a summer spent in the open country is a wonderful thing for any boy or girl. They come back home in the fall with clear eyes, full of energy and the picture of health. It seems a pity that children must be reared in large cities and are deprived of freedom and healthy conditions surrounding country life. The life of large city dwellers is altogether abnormal. However, it is readily admitted that the cities afford the best protection against infectious disease. The water and milk supplies are guarded, the excreta properly disposed of, and the Health Department possesses the machinery for controlling infectious disease. People also receive better medical treatment, until today it is safer to live in the city than the country.

Safeguards for Health

Parents should be warned of the dangers from infectious disease in summer camps. They should satisfy themselves of the character of those conducting the camp, and also whether proper measures are taken to prevent infectious diseases. It is also important to be sure that the boys in camp are provided with prompt medical treatment, preferably by a doctor in camp or one very near by.

It need hardly be emphasized that those in charge of such camps should be of good character and need to have had experience in such an undertaking. There are many other important features, moral and physical, which require judgment and constant watch. An outbreak of infectious disease is always a very unfortunate happening which cripples the activities of the camp and gives it a bad reputation. Unfortunately, many camps are situated a long distance from larger towns and cities and much must be done with rather inadequate facilities.

Every camp should have a doctor. Two or more neighboring camps might combine and arrange for one to take the responsibility of the health of the boys and girls. It is a custom

to employ fourth year medical students or a young physician just out of school, perhaps just waiting a few months for his hospital appointment to begin. His responsibility is considerable and he should be reliable and resourceful. To him should be delegated all matters pertaining to the health of the vacationists.

The site of the camp is of some importance. It should be located on high well drained land out of the way of surface wash and not muddy. Trees are a great asset to the situation. It is well to have at least one permanent building where meals can

Boys' camp under the auspices of the Y. M. C. A., conducted annually at Phantom Lake, Wis.

be cooked and served and for recreation during rainy, raw weather. The general resistance of city boys who are not used to roughing it is of some importance as related to the development of infectious disease.

The buildings and tents should be kept orderly, dry, and neat. They should not be overcrowded. Ventilation should be obtained by open windows or tent flaps at night. The bedding should be aired daily. The tent sides should be raised and the cots put out of doors on clear days.

The sanitation of all camps should be approved by the State Board of Health. The Board should lay down practical rules and these should be observed. The most important functions of the Board should be to safeguard the water and milk supply, to insure the disposal of excreta and

garbage, and advise in case of an outbreak of infectious disease. State inspectors should visit all such camps.

The water supply should be from a well which is some distance from privy vaults and on higher ground, and the well should be protected by curbing which does not leak and it should always be clean and should be in a safe situation as regards to human habitation. Lake or river water should be boiled if used for drinking provided there are any habitations near the shores.

The milk supply should be scrutinized carefully. Whether it comes from a neighboring farm or from the camps' own herds, it should be milked by healthy milkers who are clean milkers. The cans should be washed and scalded thoroughly as soon after emptying as possible. The milk should be cooled at once by ice or cold well water and at the camp should be kept in cold well or ice water.

The common privy will generally have to be used. It should be located at a little distance from the camp on a lower situation, away from the shore of a lake or stream. The vault should be about four feet deep and the privy screened from flies. Road dust or loam should be thrown into the vault once daily.

There are on the market chemical closets which are used quite extensively in the South. They are tanks filled with disinfecting solutions into which excreta fall. They are contrived for easy emptying. The excreta should be buried some distance away from camp on lower ground.

It cannot be too much emphasized that indiscriminate defecation and urination should not be allowed about any camp. Both feces and urine may be washed or leach into the water supply of that camp or another nearby; besides, it is filthy practice.

Garbage should be promptly disposed of and not allowed to lay about collecting flies. It should be deposited in a covered receptacle and this should be regularly emptied and the can washed out. It should either be buried or given to hogs. In place of cans a large pit may be dug near the kitchen and after each meal the swill

thrown into it and covered with dirt.

Kitchen and wash water should not be thrown about indiscriminately. Another pit three or four feet deep and about three feet wide in diameter should be dug and filled with round stones. The size of the pit of course will vary with the need. The waste from the sink should run into it and other liquid waste thrown into it.

The kitchen, if in a frame building, should be screened. It should be kept neat and clean.

Health Practices Enforced

There is some danger from infection through soiled dishes. This has been fairly well shown by the army experience. Dishes should be washed in as hot water as the hands will stand. It is important that it be changed frequently enough to keep it hot and not too dirty. After washing, the dishes should be scalded well with boiling water and allowed to dry. If dish towels are used for drying them they should be washed with hot water and soap after each meal.

At least one room in a permanent building should be set aside for the sick. This room can be used for isolation purposes, as well as for those who are not infectious. It should contain one or two beds, bed linen, chairs, table, and a stand on which may be placed a basin for hand washing and another for antiseptic solution. A bar or liquid soap, and a scrub brush should be provided so that the hands can be washed well after handling an infectious patient. Sulphonaphthol, which can be used for infections, should also be provided and a solution (warm water) a teaspoonful to the quart of warm water will serve as a disinfectant after washing with soap

and water. Paper towels should be on hand, if possible, for use. Small hand towels or clean pieces of cotton cloth may be used, each once only before being boiled and washed. (To sterilize the hands, they should be immersed in the antiseptic solution for at least one minute.)

Some kind of an outer garment—a hospital gown or a linen duster—will serve for the doctor when he examines a patient and the patient's attendant.

No dishes or utensils should be removed from the room without being put in a pan and boiled ten minutes before washing. All linen removed should be boiled before washing.

After the discharge of a patient, blankets, comforters, pillows, and mattresses should be aired under direct rays of the sun at least several hours. The bed and other furniture, door knobs, etc., can be washed with soap and water.

Admission Examination

Non-boilable things like shoes, watches, thermometers, etc., can be washed with soap and water and sulphonaphthol solution.

In case a room in a permanent building is not available a separate tent may be pressed into service and provided as already described.

To avoid the introduction of infectious disease it is essential that every boy receive a physical examination before he is admitted to the camp. The family physician can be called upon to do this but it is an added precaution to have the camp doctor do it over again as soon as the boy arrives. A card should be made out for each boy with name, age, home address and on it should be put down

the past diseases which he has had, particularly contagious diseases, and his complete physical examination. This card not only suffices for the purpose of recording facts helpful for the prevention and control of infectious disease, but furnishes the doctor data on which he can judge the kind of sports a boy is physically able to enter into without detriment to his health.

Preventive Measures

To avoid infection, wounds, small or severe, should receive prompt attention. They should be cleaned and some antiseptic solution applied and dressed with sterile gauze. Subsequent dressings should not be neglected. In case of deep puncture wounds, from nails, etc., or revolver or gun shot wounds, tetanus antitoxin should be administered. The danger of tetanus from punctured wounds when camps are in the woods is very slight; but if they are situated in the neighborhood of farms where horses and cattle are kept there is always a possibility of tetanus infection. Blank cartridge wounds should always call for antitoxin at once.

Outbreaks of Disease

In discussing what should be done when infectious disease develops, first consideration should be given to the fact that boys' camps are not properly provided for the care of the sick. If it is a slight illness of slightly infectious nature such as tonsillitis, acute "colds," for diarrheal conditions the patients may be kept in camp. Otherwise, the patients should be sent home, if it is not far away, or to the nearest hospital. This last principle holds good for all serious

non-infectious disease and for injuries.

Each of several common infectious diseases will be discussed separately. The camp doctor should be prepared to carry out measures to properly care for the sick, protect those exposed, and avoid breaking up the camp's vacation activities if possible.

Diphtheria and Scarlet

All sore throats should be looked upon with suspicion and at once isolated, and the camp should be provided with sterile swabs for taking cultures. These cultures can be mailed to the nearest laboratory. If a case of diphtheria develops the patient should be sent to the nearest hospital, or to a private home in an emergency, by automobile or ambulance and not by train unless absolutely necessary. This method of transportation should be practiced for all infectious diseases. Cultures should be taken once at least from all members of the camp and all carriers sent home or to a hospital. For a week subsequent to the last exposure throats should be examined daily so as to be able to detect early and secondary cases. After the end of the period for a week or two, careful watch should be kept for sore throats. There is no need of closing the camp unless several cases develop.

When a boy or girl is found to have scarlet fever he or she should be sent to the nearest hospital, or home as the case may be. Every other member of the camp should be examined carefully daily for a week after the last exposure. A list of those who have had scarlet fever should be made and these should receive the most attention. Every sore throat occurring at such a time, whether there is a rash or not, should be treated as scarlet fever. If the first case has been promptly detected and removed, secondary cases are rather unusual unless there is a carrier or a mild overlooked case in camp. In looking over the camp members at the first examination each should be asked whether he has had a sore throat within three or four weeks or whether by chance there had been scarlet fever in his family before leaving home. Suspects should be isolated in camp or if the suspicion is strong they should be sent home or to a hospital.

Control of Measles

It is difficult to control this disease because by the time the first case is recognized, which is usually at the beginning of the eruption, the patient

has been infectious for three or four days.

The first patient should be sent home or to the nearest hospital at once. All other members of the camp should be examined and those who give no history of measles should be sent home. Secondary cases will not develop for two weeks so that they will not be infectious during the trip home within the first eight or ten days after exposure. The rest of the camp members should be watched for two weeks after the last exposure.

Whooping cough, while not likely to develop, may be quite crippling to a camp. The first patient should be sent home or to a hospital at once. It is quite likely that secondary cases may not develop for so many children have had the disease. The open air

Scouts' camp at Central Valley, N. Y.

life will also be a factor in preventing its spread. However, all who have not had the disease should be watched carefully for any cough and all such should be isolated, put in a separate tent until the diagnosis is made. If it proves positive the boy should be sent home. It will hardly be necessary, unless the disease is well under way when discovered, to send home all those who have not had the disease.

In case of mumps the first case should be sent home or to the hospital at once. All other members of the camp should be examined and suspects isolated in a tent for observation. All of these who have not had the disease should be watched daily for three weeks after the last exposure and each case sent home or to the hospital as it develops.

In the event of the occurrence of epidemic meningitis every case developing should be recognized early and hurried to the nearest hospital, for treatment should begin early. After this, very close watch should be kept of all members of the camp and all with headaches, rhinitis, and sore throats should be isolated and observed. It is not practicable to detect carriers but daily observation of the camp members should reveal secondary cases at the earliest possible moment.

If not very ill, boys sick with tonsillitis may remain in camp; otherwise should be transported home or to the nearest hospital. If kept at the camp, they should be isolated until fully well.

Typhoid Fever Occurrence

The patient should be removed at once, preferably to a hospital. The investigation of the source of the disease should be left to the State Board of Health or the nearest Health Officer. The camp doctor or other general practitioner is not qualified. Investigation should be instituted for the source of the disease. First of all, the members of the farm house from which the milk comes should be examined for mild or frank typhoid fever. If the history, Widal test or examination of the stools reveals that any one in the household has ever had typhoid, the source of the milk supply should be changed. Milk should be boiled pending investigation.

The water supply next should be examined. A sample of the drinking water should be taken by a state inspector who has an outfit for the purpose. Examination for the *Colon bacillus* will determine whether it is polluted with excreta. If it is, the water supply should be changed. Examination for the typhoid germs is useless. In case of suspicion, during investigation all water for drinking or used in the preparation of food should be boiled.

Each member of the camp should be questioned and examined, laying stress on the previous history of typhoid fever at any time, a recent attack of diarrhoea or continued fever. All such suspects should be sent home.

When patients are sent home or to the hospital a history of the case should be sent along, and when contacts are sent home a history of the exposure should be furnished to the parents.

For making daily examinations the members should be lined up for sick call and every one questioned about

how he feels, and if not well, should be asked to step forward and later examination carried out carefully, including temperature. The doctor should scrutinize each boy carefully as he passes along and have any who do not look well step forward for later inspection. He should have throat sticks in his pocket and if he is watching for a disease with a rash the boys should be stripped to the waist, when responding to a sick call.

He should use some of the older

boys to help him in his examination or to care for the sick in the isolation room or tent until they are sent away. It is well for him to pick out two or more boys at the opening of the camp and give them a few simple instructions about caring for the sick, so that they can act as his assistants.

Home isolation methods should be carried out, for each camp affords many if not all the features of equipment found in the country home and the rest may be improvised.

Comfort in a Summer Camp

AS THE camping season approaches, the lure of the open is upon the multitude and a vast exodus occurs from city to country, from workshop to field and stream. The vacation period, however, is not an unmixed blessing, as it is too often marked by a parallel in the periodicity of certain diseases. Vacation typhoid is still an entity in many communities. This periodicity of disease may be held to include a drowning season, and even the accidents which are subject to increase at certain seasons.

Medical literature is full of warnings to an unsuspecting public as to dangers in health from the radical changes of habit involved in camp life. Water is to be boiled, milk microscopically scrutinized.

Most of the health tenets for vacationists are in the way of prohibitions. With relaxation there must, of course, be no lapse from the well ordered habits that are the fundamentals of health. The facts stand that people are often harmed instead of helped by their vacationing. California has had to make the most stringent regulations to avoid the despoiling of her mountain camps. Michigan has a mobile laboratory, which became a health necessity to avoid the pollution of her streams during the summer season. Wisconsin has made special rulings regarding the authority of state and county health officials over the nomadic camping public.

With the general direction of public attention toward camp supervision and the sanitary codes drawn and enforced, it is to be expected that the menace to public health from the careless vacationist will soon be reduced to a minimum. There will also be developed standard hygienic codes for each community, so that the intelligent vacationist by giving the matter proper forethought may safeguard himself against any needless

ment would depend on the locality. Plainly, an outfit of clothing and equipment that is ample for the seashore would need to be modified for a rugged situation in high altitudes. Clothing should be substantial and adapted to the location, and simple if roughing in the open is to be a pleasure instead of a hardship.

Neither is the camping trip to be a period of reckless strenuousness. Moderation should govern the stunts undertaken by the tenderfoot and there needs to be comfort in the camp after the fatiguing sports of the day. Cots, pillows, chairs, tables, cabins, must be chosen to contribute to the physical and mental relaxation which should be the common purpose of the campers.

A very sane point of view has developed out of recent studies of the human body from the viewpoint of physics. The human body is more and more coming to be regarded as a reacting mechanism, subject to laws of physics and chemistry for the maintenance of its normal equilibrium. The fatigue studies which have lately been so much in the foreground are based largely upon bodily mechanics. Motion studies have been made to clear up the conditions which account for wasted energy and result in undue fatigue. Individual energy potentials are now electrically measured. The work of one prominent writer has become identified with "mind-energy" as a source of dynamic power. Research workers seeking out the psychologic factors involved in fatigue have set themselves the task of penetrating the "mechanical processes of

The spirit of the woods is here. The experienced camper carries his comfort with him. In surroundings like this the sunshine and fresh air cure becomes immediately and permanently effectual.

Salvaging Humanity a Social Necessity

Increasing Emphasis Must Mark the
Responsibility of Society to the Individual

BY JAMES P. MUNROE, VICE-CHAIRMAN, FEDERAL BOARD FOR VOCATIONAL EDUCATION, WASHINGTON, D. C.

AS INDIVIDUALS and as a people, we were raised to such a pitch of fervor during the war that it is a cruel awakening to find that this exalted spirit was, in the main, temporary, and that the white flames of patriotism, like those of other fires, end in a heap of ashes. It is too soon to appraise the good which is certain eventually to come from that period of moral enthusiasm and it is too early to evaluate properly the evils which are conspicuous accompaniments of the "ashes" stage in which the United States now finds itself, rather dishearteningly, to be.

One of the most outstanding of the material evils is the unscientific and seemingly wasteful way in which the salvaging of the vast army and navy stores left on the national hands by the sudden stopping of the war is being done. In the belief that the end was much farther away than proved to be the case, munitions and other supplies essential to military success were accumulated in almost unbelievable quantity. To have thrown all this suddenly upon the market would have been, of course, disastrous; but it is even worse to permit so much of this valuable material to go, as there is reason to fear that it is going, to total destruction through the rust and decay of Governmental neglect.

Much of the property created for war purposes, such as the extensive

Collective responsibility for rehabilitation, so clear in the case of ex-service men, is less poignantly felt as relates to the average man who may be an unwitting and involuntary victim of social and industrial conditions over which he has no control.

If abuses growing out of the increasing complexity of social life demand increasing individual sacrifice without a compensating conservation, then civilization is self-limited, if not self-destructive, and we must salvage waste, especially of human materials, and set up new standards of social obligation.

training camps, was avowedly temporary, and its destruction has to be accepted as a necessary waste of war. By far the greater part of the vast accumulation was, however, not of this character; but is as useful for purposes of peace as for those of war. To have worked out a comprehensive scientific method of getting this valuable material, no longer of military use, back into the channels of peace would have been another triumph to be added to those accomplished by the United States in making so quickly effective its long delayed entrance into the World War. Unfortunately, this

logical post-war step was not taken and the marked reduction of the general tax burden which would have followed such action can not now be looked for.

No one is particularly to be blamed. It is but another evidence of the fact that, as a people, we are wasteful and impatient of economies, whether the petty ones of our own households or the immense ones of that Government household which costs every one of us, directly and indirectly, so staggering a sum.

Fortunately, in the matter of human salvage, we have been much more thrifty; and one of the good outcomes of the war is that the Government has taken steps in human conservation far in advance of those followed heretofore by itself or by any other nation. The advance of thought, as well as the disquieting experiences of the World War, when we found ourselves close to national bankruptcy in the matter of men available for fighting and other military services, focused national attention, as never before, upon the highly precious nature of an educated, or even a semi-trained, man and aroused widespread public support for measures which should salvage human beings in a scientific, humane and comprehensive way.

The rehabilitation program urged upon the Federal Government from the moment that our entrance into the

This handicapped man, war-wounded, has become an expert auto-mechanic and is laying plans to start his own business when his course is finished.

This man, formerly a farmer, finds it possible to do vulcanizing with an artificial arm almost as well as his unhampered competitors. He was saved from the industrial waste heap.

war seemed probable, met, therefore, with ready response from those in authority as well as from the great body of thinking citizens. The delay through which the Soldier Rehabilitation Law was not passed until June, 1918, fourteen months after we entered the war, was due to difference of opinion as to its administration rather than as to the fundamental importance of the measure. While, of course, there were various reasons impelling the Congress to place the responsibility for soldier rehabilitation in the hands of an existing educational body, the Federal Board for Vocational Education, the controlling motive seems to have been a belief

that the dominant aim of the proposed legislation should be towards sound education for employment rather than towards the mere securing, on a haphazard basis, of a job.

Good Progress Made

The work of rehabilitating disabled ex-service men was so fruitful of good results that Congress, in June, 1920, needed almost no argument to pass the so-called industrial rehabilitation law under which the Federal Government and the states are already making good progress in dealing with the long neglected duty of saving men and women, injured in industry or otherwise, from the economic waste heap.

Although this new responsibility was placed also upon the Federal Board for Vocational Education, the problems of soldier rehabilitation and of civilian rehabilitation are in their nature quite dissimilar and call for radically different methods of administration. That of rehabilitating the ex-service man is an intensive, limited service, requiring the rapid expenditure of large sums of money by the Federal Government, which was solely responsible for the disabilities involved; while that of civilian rehabilitation is one to be worked out slowly and carefully by the states with such aid from the Federal Government in the way of initial expenditure and research as may be necessary as a stimulus. In carrying out the work of soldier rehabilitation the Federal Government has already appropriated nearly one hundred and fifty million dollars and expects to make available perhaps as much more before the work of rehabilitation, some three or four years hence, will be practically finished. In carrying forward the work of civilian rehabilitation, it has appropriated only approximately one million dollars a year for four years, believing that this will be sufficient to give that initial stimulus to the states under which the economic and social value of rehabilitation will be so fully demonstrated that, thereafter, the states will carry it forward, on an increasing scale of expenditure, as a matter of course.

Meanwhile, these states will have before them as an evidence of the effectiveness of rehabilitation, the conspicuous achievements of the Government in the matter of the rehabilitation of ex-service men. As of May 1, 1921, less than three years after the

This group of electrical men installed the switchboard shown in the power plant. The cement bases were also made and the motors placed by the same group.

Handicapped negroes at Tuskegee Institute making shoes.

Men receiving training at the machine shop of Tulane University.

law was passed, the Federal Board for Vocational Education, through its agents all over the United States (for from the beginning, its activities were decentralized, and it now has, in addition to the original fourteen district offices, over 125 local offices) has rendered decisions, through personal interviews, upon the applications of approximately 350,000 ex-service men, has adjudged about two-thirds of them to be eligible for training under the rehabilitation law and has placed in training with maintenance pay or without pay (in the proportion of about six to one) approximately one hundred thousand men.

To do this, the Board is availing itself of about two thousand schools and colleges, both public and private, and of about ten thousand industrial establishments. Furthermore, in the cases of about twelve thousand men still in hospitals or sanatoriums with diseases, such as tuberculosis, from which recovery is slow, the Board is maintaining schools and classes in which training is a matter of medical prescription as to type and hours, and where it serves the purpose both of hastening recovery and of shortening the subsequent period of vocational training. Moreover, to meet the needs of non-English speaking men, illiterates, and those for whom it is difficult to determine the most suitable line of training, the Board has established, at strategic points, training centers, under its own teachers, where the day's work is individualized for the purpose of remedying each man's special deficiencies and of trying him out as to his most promising road towards vocational competence.

Experience with this wide range of men, at least half of them below the median from the educational standpoint, and all of them below par from

the physical standpoint, has demonstrated that from the economic aspect alone, the salvaging of men is an investment which brings in colossal returns. Were the work of soldier rehabilitation eventually to cost the Government half a billion dollars, it will bring back to the country in increased earning capacity of the men so trained, at least four times that sum.

The social good resulting from rehabilitation, however, is far beyond its economic results. To leave a disabled man, especially one disabled in the service of his country, to carry throughout his remaining years the burden of his handicap is not simply a waste of potential man-power; it is a social injustice under which the spirit of the man rankles and festers.

Thus neglected, he would feel justified in assuming the rôle of a parasite either upon the Government or upon society and there would thus be created a body of pensioners and beggars which, while living upon the taxes or the alms of their fellow-citizens, would carry always a deep-seated grudge against society for having compelled them to be liabilities instead of assets in the body politic. Like any other social sore, such a disaffected body would be not only evil in itself, but would infect a widening circle of others incited by this injustice to hostility against the whole social order or debauched by its example into a similar attitude of dependency.

To make deliberate and far reaching plans for rehabilitating the com-

The Ohio Mechanic Institute, where handicapped men earn their way as lithographers.

This room was especially constructed for Federal Board training. The men receive eight dollars a week to start, increasing as they gain facility.

paratively large body of men disabled in the World War, to relieve them, while being trained, from financial anxieties, and to see to it that they are not only restored as wage earners but are cured, so far as may be, of deficiencies of language and of lack of knowledge of those other attainments essential to good citizenship, has saved the United States from that worst of menaces, a widespread disaffection rooted in clearly recognized injustice. The case for the industrially disabled is not so clear, of course, as for those injured in a war for national preservation. It is equally plain, of course, from the economic standpoint; but from the social point of view one must go a little deeper to find full justification. That justification rests on the fact that, while a certain proportion of civilian disabilities are due solely to a man's or woman's own carelessness or defiance of the laws of health, by far the greater number are due wholly or in great part to the conditions of economic or social life over which the individual has absolutely no control, but concerning which society could, if it chose, exercise far greater watchfulness than in fact it does. In other words, the vast majority of accidents and of disabling diseases are due to the increasing complexities of modern life only in slight degree controlled, as yet, by social regulation. So large a proportion, therefore, of civilian disability is the fault of society rather than of the individual, that there is as substantial justification, from the social stand-

point, for the rehabilitation of those disabled in the normal pursuits of peace as for those injured in the abnormal pursuits of war.

Whether, therefore, we view rehabilitation from the purely monetary aspect, that of conserving workers who heretofore have been most wastefully thrown aside, or whether we regard it from the deeper and more enduring point of view of the good of civilization, it is seen to justify itself as one of the most important forward steps towards social well being that this country has ever taken. Theoretically, the arguments are unanswerable, and practically, those arguments have been proved as sounder even than their advocates believed, by the satisfactory economic and social results already achieved in connection with the rehabilitation of ex-service men. With such a demonstration as this, the states should have no hesitation in providing a generally similar scheme of rehabilitation for the immensely greater number of those disabled in the pursuit of their vocations or of their avocations, or even in the hazardous process of getting, under modern traffic conditions, from one place to another.

Trains Dental Hygienists

A course for training women dental hygienists will be offered at the University of Pennsylvania Dental School, in September, at the request of the State Department of Health. The purpose of the course is to train women to serve as teachers in schools, hospitals, and private dental offices,

and to make them capable of thoroughly cleansing the mouth and teeth, and discovering the need of expert dental attention.

A Challenge to Conscience

In the United States in 1919 one mother died for every 185 babies born, and every eleventh baby born died before he was a year old. That these rates are excessive is shown in "Save the Youngest," a bulletin issued by the United States Department of Labor through the Children's Bureau, and just revised to compare the latest rates for the United States with those for foreign countries.

Six countries are shown to have a lower infant mortality, and sixteen in a group of seventeen—a lower maternal mortality than the United States. Not only do we lose more mothers in proportion to births than practically any other civilized country, but we apparently lose more on an average each year than the year before. Whereas in other countries there has been a decrease in the death rate from childbirth, the rate in the United States rose from 6.1 per 1,000 births in 1915 to 6.2 in 1916, 6.6 in 1917 and to 7.4 in 1919. Moreover, in this country there is no appreciable decrease in the proportion of babies who die from causes largely connected with the care and condition of the mother.

Experience has proved, the bulletin points out, that thousands of deaths of both mothers and children could be prevented every year by public measures for the protection of maternity and infancy. In New York city among 4,496 mothers who were supervised by the New York Maternity Center Association before and after the birth of their babies, the maternal mortality rate was less than one-third the rate of the United States and the rate for deaths in early infancy was less than half that for the city as a whole. In other cities of the United States and in foreign countries the institution of infant welfare measures has been followed by greatly decreased rates.

Measures which have proved successful in preventing this waste of life among mothers and babies include the following: Prompt and accurate birth registration, health centers, public health nurses, special clinics, trained attendance at childbirth, adequate hospital service, education of the mother in maternity and child hygiene, and education of the general public in the significance of an necessity for maternal and infant health.

The Health and Welfare of Postal Employees

AN INTERVIEW WITH HON. WILL H. HAYS, POSTMASTER GENERAL, WASHINGTON, D. C.

THE announced intention of Postmaster General Hays to improve working conditions of postoffice employees has attracted much attention throughout the country. Mr. Hays' statement that he intends to have a Welfare Department in the Postal Service with as definite duties as those of any other branch of work has brought much speculation as to the manner in which the Postmaster intends to carry out the work. The appointment of Lee K. Frankel, vice-president of the Metropolitan Life Insurance Company, and one of the best known experts in health and welfare, as head of the new Welfare Bureau, has just been announced as the first step in the new program.

In response to a request from the NATION'S HEALTH, Mr. Hays, for the first time, outlined his plans for the new Welfare Department. He says:

"I have visited some of the larger post offices and viewed working conditions personally. I have had a number of postmasters from the larger post offices, representatives of the employees, and welfare workers from several large industrial plants in conference concerning welfare work in post offices.

"From my own observation, and what has been gathered from the conferences of postmasters and employees, it is very certain that a great program of improving working conditions among the employees of the Postal Service awaits us.

"We are going to have a welfare department in the Postal Service just as definite in its duties and certain in its functioning as the fiscal department or any other department. It will be in charge of an individual competent to look after it, doing nothing else. Every other large industry in the country has adopted welfare measures. This humanizing business is not original. It has been the definite trend of American business for the past generation. Just how far I can go with it in the Post Office Department I don't know, but it is certain that very much can be done and not in any sense in lieu of wages. All the things that are done successfully for the welfare of the employees in other successful business must be done as far as possible in this, the greatest of all businesses. Why it has not been seriously undertaken be-

fore in the Post Office Department it is difficult to understand. It is certainly one of the very definite purposes of the days just ahead. If we can improve the spirit and actual conditions of the 300,000 men and women who do this job, that in itself is an accomplishment, and it is just as certain to bring a consequential improvement in the service as tomorrow's sun.

"The question of providing facilities to improve working conditions of employees has been left to each individual postmaster of the larger postoffices, numbering several thousand. It is unfair to expect this initiative on the part of these postmasters, although I was pleased to learn that some postmasters at the larger offices had provided certain benefits to employees at their own private expense. But for the most part welfare work is almost unknown in the Postal Service. This is not unnatural, when the limitations in Government are known.

Definite Limitations

"The post office buildings are under control of the Treasury Department, not the Postoffice Department. When a dark, dingy room needs painting to give light to it; when alterations are necessary to give ventilation; when space is required for a rest room and a lounge to place in it, these things must all be obtained through another department of the Government.

"If first-aid remedies are required; if a chiropodist is engaged to look after the feet of such employees as carriers or distributors; or the use of a woman attendant for the women employees is desired, more or less restrictions operate against obtaining these. All of these benefits and very much more in the direction of welfare work are provided by private institutions for their employees with full public approval and commendation. To these wise managers of private business it is not alone altruistic, but plain common business sense. To propose something like this among Government employment meets with the prejudice of some that the Government employees have sinecures and fat jobs and are not entitled to this consideration. There is no occupation in any line of work which calls for a higher grade of intelligence and for more real, hard labor than in the

Postal Service. The postal workers are a hard working class of employees. We have just got to get away from the idea that Government employees are to be less favorably treated than those in private employment.

"The one most important element in any service is the spirit of the men doing it. And we must get away in the post office service from any idea that labor is a commodity. I would reiterate the suggestion that that idea was abandoned 1921 years ago. I am determined in all seriousness to go to great lengths to develop the spirit in the Department that we are three hundred thousand partners. The working conditions, in many places, are unsatisfactory and a large amount of work must be done in that direction. There is no doubt about the quality of our employees. They have the brains and they have the hands to do this job well, but some place along the line the heart has been lost out of the works.

Institution for Service

"I have said that it is my opinion that the Postal Establishment is most certainly not an institution for profit nor for politics, but an institution for service and it is the President's most earnest purpose to improve that service. You can't expect men and women to give service if they are to be shuttled out of politics. It would be my very greatest satisfaction if in this effort I contribute a little to the end that the Postal Service be made more and more a desirable career into which the young enter with a certainty that their service will be performed under reasonable conditions for a reasonable wage and for an appreciative people. The men and women who constitute the great army of employees are doing a distinct Government and public service and they are entitled to an appreciation commensurate with the efficiency and importance of that service. The first element of a proper appreciation is to make certain that honest and efficient service shall be honestly recognized and that the merit system shall control without any subterfuge under any circumstances whatsoever. I have said, and I repeat, that my purposes are: (1) To make such rectifications as in all decency and fairness must be made to assure a

square deal; (2) to strengthen and broaden the Civil Service at every point wherever possible to the end

that merit may govern; and (3) with absolute fidelity to put the entire service upon a purely business basis so

sound and so serviceable that no political party will ever again dare attempt to ignore or evade it ultimately."

A Child Welfare Station in France

By A. C. BURNHAM, M.D., PARIS, FRANCE.

OF INTEREST to Americans because founded in part by funds furnished by the American people, and because it represents a particular phase of the after-the-war movement for the improvement of health, the child welfare station shown in the accompanying illustrations serves as a tangible evidence of what has already been accomplished and gives every indication of a continuation and ultimate extension of the work.

The official name of the station is the *Ecole de Puériculture de la Faculté de Médecine de Paris*. It is called a school rather than a clinic or health station because it is used not only for the care of children but also for instruction of both medical students and visiting nurses.

Franco-American Foundation

The *Ecole de Puériculture*, located in the city of Paris, was started in January, 1920, upon what is known as a "Franco-American Foundation." The grounds, buildings, and personnel were furnished by the French, while America, through the American Red Cross, contributed a substantial sum of money which was turned over to the *Faculté de Médecine* for the installation of equipment and conversion of the buildings to their present use.

As will be seen by the pictures, the buildings consist of several one-story wooden buildings connected by a cen-

tral corridor. These buildings were formerly barracks and were occupied as such during the war. They are not unlike thousands of similar barracks in the United States, but are of interest because they demonstrate a definite peace time use for buildings of this type. They have been lined with half inch sheathing, joined together by a central passageway, and piped for water and sewage disposal. They are lighted with electricity and heated by a number of coal stoves. One pavilion is devoted to administration offices; one to admission of patients and social service; one to children less than three years of age; one to older children; and one to prenatal cases. There are also a lecture room, clinical and x-ray laboratories, and a well equipped dental clinic.

To the American reader there is nothing unusual about the building except that it compares very favorably with the average out-patient dispensary, and that it represents one method of utilizing the temporary barracks left vacant after the war.

The most interesting thing about this particular dispensary is that its work is limited entirely to prevention. It is what might be called a "well baby dispensary." Children are weighed, examined, and advised as to food, exercise, etc., excepting advice as to feeding for cases of undernutrition, little or no treatment is furnished. Sick children are either

sent to hospitals or referred to private physicians. The *Ecole de Puériculture* is a preventorium in the sense that children are reached before they become ill, and the attempt is made to keep them in good health.

There are three separate services; one for prenatal care, another for nursing mothers and infants, and the third for children from three to six years of age. In addition there are what is known as the "Service des Spécialités," which includes radiography, dentistry, laryngology, and clinical pathology. In addition there are departments of nursing instruction, social service, athletics, and distribution of milk. During the last year 1,909 families were under observation.

The prenatal clinic is held twice a week. Expectant mothers are examined and advised. Extra feeding in the form of milk may be furnished, but no attempt is made to treat pathological cases, nor to care for the actual delivery. Accouchements are made either by private physicians or in hospitals.

The clinic for young children and nursing mothers is held daily. The attempt is made to continue breast feeding in every case. If necessary, the mother may be given extra food; or, if thought advisable, milk may be furnished the baby for supplementary feeding. The clinic for older children is held once a week and the special

Typical mothers with their babes in the waiting room of the infants' clinic. Note the healthy appearance of the babies and the expectant interest of the mothers.

services once or twice a week as may be necessary to cover the requirements of the service.

At the clinic for nursing mothers and infants, there was a total attendance of 4,962 during the year and at the clinic for older children 1,006. The prenatal clinic which is held twice a week had a total attendance of 1,121 (visits). The special services were not started until late in 1920 so that the total figures for the year are not available.

The Ecole de Puériculture is said to be the first school in France to offer an official diploma for instruction in visiting nursing. The course is for one year and is open to nurses who have had preliminary training. The course includes classes in child hygiene, milk modification, visiting nursing, social service, etc. The Faculté de Médecine offers a diploma to those nurses who complete the course. There is also a shorter course leading to a certificate. Visits are made to the homes by nurses, who have completed training, accompanied by one or more student nurses. During 1920, a total of nearly nine thousand visits was made.

Personnel

The character of the physicians associated with this work is such that its success is assured. Professor Pinard is director, and Professors Couvelaire, Merfon and Leon Bernard are in charge of the various services. Doctor Weil-Hallé is secretary of the faculty and assistant chief of the service for infants and nursing mothers. Twelve other physicians serve in the various clinics and special services. Including the permanent nursing personnel and non-medical employees, there are a total of twenty-five other persons who either devote part or full time to the work of the school.

Ecole de Puériculture, Paris, showing the use of military barracks: Child welfare, medical instruction, and training for nurses.

One of the most important forms of welfare work undertaken by this institution has been the distribution of milk to undernourished children. The city of Paris furnishes milk free of cost to children who require additional feeding. The only requirements are that the child's parents are financially unable to purchase extra milk, and a physician's certificate that such extra food is necessary. The Ecole de Puériculture has undertaken the examination of children in three wards in Paris and the distribution of the milk to such children as require it. The child must visit the clinic for examination at least once a month so that progress may be observed. The quantity ordered by the physician is sterilized and bottled at the milk station in connection with the Ecole. The milk bottles suitably labeled with the child's name are delivered to the local grocery stores where they may be easily called for. This service has been of great value to both the clinic and the city. It has enabled the clinic to keep definite records of children

before the school age, which are usually very difficult to secure. It has also made it easy for the city to get the free milk into the hands of those who most deserve it.

The entire experiment represents a distinct forward step in preventive medicine in France. While it is as yet too early to obtain comparative morbidity and mortality statistics, the value of the work from an educational standpoint is plainly apparent.

The character of the work done during the first year promises excellent results in the development of the child welfare program throughout France.

The thoroughgoing effort to obtain in every case the full background of causes makes the work of child care in France a social study of immense value, its relief a social experiment on unprecedented scale, and the concurrent awakening of public conscience and public initiative in prevention as well as cure marks the rise of a new social ethics.

Masonic Hospital Rebuilds Crippled Children

By S. P. MOORE, CHICAGO

A BRIGHT spot that appears in the somewhat discouraging outlook upon the general inadequacy of state and private provision for the care of life's handicapped appears in the many evidences of a broadening conception of what such service really should include.

Formerly the social attitude toward men who were crippled in war was one of commiseration, but the only palliation offered was a pension pittance that meant dependence always. For the industrially crippled, the situation was even more hopeless and they were the vicarious sufferers of a system that took no consideration of either cause or effect, fixed no responsibility, and attempted no remedy.

For the crippled child, formerly regarded as accursed of God, long subjected to neglect, there was finally provided physical care and, eventually, as orthopedic measures became more precisely adapted, corrective surgery gave the little crooked bodies a better chance.

But an attitude more spiritual and more creative in approach marks the recent attempts of society to discharge its obligation to the crippled child. It is by no means adequate service to see that these unfortunates are properly housed and fed. Not even the correction of remedial deformities is sufficient.

In a recent book on "Child Welfare from the Social Point of View" Nora Milnes¹ discusses the economic back-

ground of conditions which cause undue suffering on the part of the handicapped child. "Brought into the world without its desires having been consulted, condemned, unless help be forthcoming, to live a life of suffering, the child makes an appeal that only the hardest can resist. No man and no woman can see a child suffer without themselves suffering. The sick child is probably the saddest of all sights; ill before he is old enough to find solace in those occupations that at least shorten the days of convalescence for those who are older; ill when too young to describe what he is feeling, and perhaps ill through preventable causes, he forces a claim upon the sympathies that the sickness of those who are older can never arouse, and from this root of sympathy there blossoms a determination to alter life."

When the needs of the crippled child are fully met, there will be involved preventive medicine and social measures to remedy malnutrition and many of the basic causes of deforming conditions in children.

Even at best, the end results, physically, for the crippled child are problematical, and corrective measures extend over such prolonged periods that unless his education proceeds parallel with his treatment, he is unhappy and discontented from lack of occupation, and is retarded mentally so that what in the first instance was a physical drawback becomes a hopeless handicap in any competitive effort, either in earning a livelihood

or in those creative efforts which are the final expression of real living.

The keynote of the reconstruction undertaken by such institutions as the Scottish Rite Hospital for Crippled Children at Decatur, a suburb of Atlanta, Ga., is that in these children the privilege of individuality is recognized. The utmost orthopedic skill is combined with appropriate régime under the most favorable circumstances is employed without interruption of their general education. There is also such special training as the particular handicap and economic need of the individual may indicate; but, aside from any immediate or future need to compete with others in earning a livelihood, such a course gives these crippled children the advantage of intellects fully trained and of mental resources which are productive of a balanced and normal attitude toward life.

It is coming to be appreciated that even a marked deformity is destructive of personality only when through neglect it is permitted to repress individual development. Hence the significance of any single enterprise which takes care of the handicapped children of a given group, and the great social value of wider movements like that in Iowa, where responsibility is assumed by the state in such matters and through the medium of the University of Iowa the medical and educational departments unite to extend complete care to all indigent crippled children within the bounds of the state.

What is the meaning of a life that is deprived of all stimulus of competitive effort?

National Health Departments in Review

BY HOMER N. CALVER AND JAMES A. TOBEY, WASHINGTON, D. C.

HEALTH has been a matter of public concern from very early times. The ancient Hebrews had a system of medical police, the Greeks appointed public physicians, and the Romans are famous for their public sanitary engineering. Probably the first real Board of Health was that of the Venetian Republic, appointed in 1348 as a result of the ravages of the Black Death. In 1762 a sanitary council was established in every Prussian province and England passed a number of health laws at the beginning of the nineteenth century. The second great pandemic of cholera from 1840 to 1850 resulted in the organization of *Conseils d'Hygiène* in France in 1840 and the Public Health Act in England in 1848. The first board of health in this country was that of Louisiana, established at New Orleans in 1855, and followed by those of Massachusetts in 1869, and California in 1870. The yellow fever epidemic in 1878 led Congress to create a National Board of Health, which went out of existence because of lack of appropriations. Its place was taken by the United States Marine Hospital Service in 1883, which became the United States Public Health Service in 1912.

Society Fosters Health

Today practically every civilized country takes official recognition of its responsibility to protect the public health and maintains a national organization for that purpose. In most cases the health functions are

placed under the jurisdiction of a government department, such as the Ministry of the Interior, and constitute a bureau in it. In every country there is generally at least some form of local health administration. Sometimes, as in our own country, several government departments perform health functions. As knowledge regarding the science of government advances, however, nations begin to realize that efforts to preserve and promote health should be efficiently coordinated and administered. To this end there have recently been established a number of Ministries of Health, the executives of which are responsible directly to the head of the government.

There are at present about a dozen such independent national health departments. In the following pages will be presented a brief review of each, followed by a list and data on other countries the health departments of which are not yet full fledged independent ministries. This review is not a survey of world health activities. Such a study, showing the administration, finance, operation, functions, and results of *all* health departments of the world would be interesting, valuable, and would represent a stupendous piece of work, which some organization of international scope may some time find it worth while to make.

The data presented below has been gathered from reports, articles, from embassies in Washington and, with respect to South and Central Amer-

ica, from the Pan-American Union. It has been in process of collection for some time and since changes in governmental procedure are likely to be rapid in these days and no respecters of writers of articles, there may be some inaccuracies. If so, let the magnitude of the task of attempting to keep in touch with mundane health activities excuse them.

Independent Departments

(A) *Great Britain.*—In England and Wales the Ministry of Health was established on June 3, 1919, and on July 1, 1919, took over all the powers and duties of the Local Government Board, the Insurance Commission, the Welsh Insurance Commissions, and the powers of the Privy Council relating to midwives. The powers of the Board of Education regarding the health of mothers and young children, and of the Home Office in relation to infant hygiene, were transferred to the Ministry on October 1. On December 1, the powers of the Board of Education with respect to medical inspection and treatment of children and young persons were taken over, though parts of this work were to be carried out by the Board under the direction of the Ministry. In May, 1920, other health functions of the Home Office, the Secretary of State, and the Board of Education were transferred to the Ministry. There are eight departments in the Ministry of Health, as follows: general health and epidemiology, maternity and child welfare,

Pan-American Union.

tuberculosis and venereal diseases, supervision of food supplies, general practitioners' services, sanitary administration in relation to infectious diseases, Welsh Board of Health, and the special medical staff. The Chief Medical Officer is Sir George Newman and he has a staff of nearly one hundred health workers. The first annual report of the Ministry has recently been issued in four parts, namely: Part I, dealing with public health, local administration, local taxation and valuation; Part II, with housing and town planning; Part III, with administration of the Poor Law, the Unemployed Workmen Act, and the Old Age Pension Acts; Part IV, with the administration of National Health Insurance, and the Welsh Board of Health. Scotland and Ireland have Ministries of Health similar to that described above.

The Dominion of Canada has a federal department of health under the administration of a minister. This department has a division of quarantine service, a division of medical inspection of immigrants, a division of marine hospital service, and a division of food and drug laboratories. The quarantine service is divided into the Inside Service, headed by the Director General of Public Health, and the Outside Service. The bureau of statistics is in the Department of Trade and Commerce. Of the nine Canadian provinces, which correspond to our states, New Brunswick has a Ministry of Health, Alberta a Ministry of Municipalities and Public Health, Ontario a Ministry of Labor and Health, and the others are without such organizations.

New Zealand has a department of public health in charge of a minister, who is also Attorney General, Minister of Immigration, Minister of Education, and Minister in Charge of Hospitals.

None of the other British possessions have national independent departments. Of the six states of the Australian Commonwealth, Victoria has a ministry of Public Health and Labor, and Western Australia has a Ministry of Education and Public Health.

(B) *France*.—France has a Ministry of Hygiene, Assistance, and Social Welfare, which was created under the Millerand Ministry in January, 1920. As a nucleus, the new Ministry of Hygiene took the Bureau of Public Assistance and the Bureau of Public Hygiene from the Interior Department, and the Bureau of Social Welfare from the Labor Department. The program includes repopulation,

reduction of infant mortality, control of communicable diseases, anti-tuberculosis work, venereal disease control, installation of dispensaries, hospitals, and sanatoriums, anti-alcoholic work, and housing. The Minister of Hygiene, M. J. D. Breton, is a chemical engineer.

(C) *Czecho-Slovakia*.—The Ministry of Public Health and Physical Education (Ministerstvo Verejného Zdravotníctva a Tělovychovy) was organized in 1918 after the constitution of the new republic was adopted. Previously Slovakia has been in the jurisdiction of the ministry of public health of Hungary and Bohemia, Moravia, and Silesia belonged to the corresponding ministry of Austria. Various laws, including obligatory vaccination, rules for cremation, and requiring medical examination previous to marriage, have

been passed. The general headquarters are at Warsaw. There is also a Children's Bureau in the Ministry of Labor.

(E) *Serbs, Croats, and Slovenes*.—There is a Ministry of Public Health in this kingdom. The Ministry of Social Politics has charge of the health problems of the half million war orphans through its Department for the Protection of Children and Youths. The Ministry of War also has a Department of Sanitation.

(F) *Brazil*.—The National Department of Health (Departamento Nacional de Saude Publica) is an independent department under the president. It has the following bureaus: (1) administration, (2) maritime and fluvial sanitation and prophylaxis, and (3) rural sanitation.

There are also sections on statistics, sanitary engineering, leprosy,

Where ancient is modern and modern is ancient. The old Roman aqueduct at Kavella, Greece, brought water to the city from the mountains. It is no longer used. The present supply is taken from highly polluted wells and sink holes and is conveyed in jugs such as are being carried by the women in the foreground.

been passed. Special councils for the famous cure places, for the control of tuberculosis, for control of alcoholism and venereal diseases, have been created. A Pasteur institution and hygienic laboratory have been established. The International Health Board has sent Prof. S. M. Gunn of the United States as technical adviser to the Ministry. Czecho-Slovakia also has a Children's Bureau in the Ministry of Social Welfare. A description of this bureau and that of Poland is given in the Eighth Annual Report of the Chief of the United States Children's Bureau (1920).

(D) *Poland*.—The Ministry of Public Health has the following departments: (1) Public hygiene, (2) child hygiene, (3) health institutions, (4) pharmacy, (5) veterinary and sanitation, (6) food, and (7) general sanitation. There are seven health dis-

tributions, medicine, pharmacy, dentistry, midwifery, food inspection, tuberculosis, hospital assistance, and child welfare. This department was created by a law signed by the president on May 26, 1920. According to latest advice, supplementary legislation to enforce it has not yet been passed, though appointments have been made.

(G) *Cuba*.—Cuba has a Department of Public Health and Charities, under a cabinet officer.

(H) *Santo Domingo*.—This country has a national Department of Sanitation and Beneficence, which was created by law January 1, 1920.

Non-Independent Departments

Belgium.—The Health Department in Belgium is styled the Administration of Public Hygiene, and its direction is under the auspices of the Min-

istry of the Interior. It consists of four bureaux: (1) hygienic works, (2) hygiene, (3) manufacture and commerce of food, and (4) the hygiene and health service laboratory. There is also a national children's bureau, directed by a board of forty members.

Denmark.—The National Board of Health administers the health work of Denmark with the Ministry of Justice in charge. This Board has no executive authority and is largely advisory. It calls the attention of local authorities to transgressions of law and inefficiency in health matters, but can take no action.

Greece.—The Medical Council of Greece assumes responsibility in health administration under the Ministry of Interior. The council concerns itself only with the suppression of alarming epidemics arising from time to time. There is in the Ministry of Communications, an agency for combating malaria. The Director of Public Health, who is not a physician, has an advisory council of fifteen physicians.

Finland.—This country has a Bureau of Medicine under the auspices of the Ministry of Interior.

Italy.—In Italy all health activities are the function of the General Board of Public Health (Direzione Generale della Sanita Publica) under the auspices of the Ministry of the Interior.

Netherlands.—The Central Council for Public Health in the Netherlands is organized under the direct supervision of the Ministry of Labor and includes three chief inspectors and seventeen inspectors of public health. The Dutch public health work is regulated by an act of June 21, 1901. The Central Council consists of three chief inspectors, seven ordinary and fifty extraordinary members. There are also public health committees in every municipality of 18,000 inhabitants or more and in combinations of communities, the total population of which amounts to not more than 40,000. The members are nominated by the Central Council and appointed by the governor of each province. They advise the local and municipal authorities and the chief inspectors. The Central Council acts in an advisory capacity on public health to the government, undertakes research, and keeps a register of physicians and allied professions. The inspectors carry on the active work, assist the public health committees, make investigations, and exchange information on disease and similar matters.

Norway.—The administration of

public health in Norway is effected through a Division of Health, Hygiene, Sanitation, and Medicine. Its chief office is styled the Ministry of Social Affairs.

Roumania.—The department having in charge the health work of Roumania is called General Health Direction, with authority under the Ministry of Interior. There is said to be a strong movement to raise this department to the rank of a ministry.

Health Under Soviets

Russia.—Russia has a Commission of Public Health under the Soviet government. This Commission is composed of fourteen sections, as follows: medical, sanitary and epidemiological, balneology, maternity and child welfare, general material and supplies, medical material, pharmacy, military medicine, naval medicine, railway medicine, medicine for waterways, finance, general administration, and elementary instruction in hygiene. It is interesting to note that a special section is devoted to the subject of baths. In the provinces there are apparently local medico-sanitary commissions which concentrate in themselves the sections on medicine, sanitation and epidemiology, supplies, etc. These local commissions have also taken over the work of the old federal, departmental and municipal departments of medicine.

Spain.—In Spain four bureaux are charged with health functions: (1) Royal Council of Public Health, (2) Section of Civic Public Health, (3) Alfonso XIII Institute of Hygiene, and (4) Ports and Quarantine. The Ministry of the Interior is the authoritative body. The Royal Council consists of the Minister of the Interior, a vice-president, secretary, keeper of records, eighteen directors by right of birth, and thirty-three directors by election.

Sweden.—The Royal Administration for Public Health (Kungl. Medicinalstyrelsen) of Sweden is constituted a part of the Department of the Interior. It has six bureaux: (1) the Veterinary Bureau; (2) Bureau for Asylums; (3) the main Bureau (hospitals, pharmacies and dispensaries); (4) the Public Health Bureau; (5) the Administrative Bureau, and (6) the "Medicinalbyran," for matters concerning appointments of physicians the Civil Service, the exercise of medical art, criminal medicine.

Japan.—Governmental health activities of Japan are concentrated under the Sanitary Bureau, with authority under the Department of the

Interior. The services are organized into four bureaux for: (1) prevention of disease, (2) quarantine, (3) supervision of physicians and allied professions, and (4) hospital supervision. In addition to the bureaux mentioned there are three special branches, one for the investigation of public health methods, one for the study of medicinal plants and the production of medicine, and one for the encouragement of the manufacture of medicine and dyestuffs.

Persia.—A twofold organization exists in Persia, namely, (1) Sanitary Council, and (2) Bureau of Health and Municipality. They are under the auspices of the Ministry of Education, and the Ministry of Interior, respectively. The Ministry of Foreign Affairs also has a sanitary section which deals with external health problems.

American Types of Service

Argentine Republic.—The National Bureau of Hygiene (Departamento Nacional de Higiene) is organized under the auspices of the Ministry of Interior. It has bureaux of: (1) maritime and fluvial sanitation and prophylaxis; (2) internal sanitation and prophylaxis; (3) school, social, industrial, and child hygiene; (4) dental medicine, supervision of the practice of medicine and allied professions; (5) bacteriological institute, chemical institute, and institute of smallpox vaccine; and (6) disinfection and drainage. The work carried on includes anti-malaria activities, inspection and disinfection of railway trains, anti-tuberculosis campaigns, school inspection, and special investigations.

Bolivia.—In Bolivia there is no special board of health. Such health functions as are exercised are under the auspices of the Ministry of the Interior.

Chile.—Health work in Chile is achieved through the Administration of Health (Direccion de Sanidad) under the Ministry of the Interior.

Colombia.—The Central Council of Hygiene (Junta Central de Higiene) is included in the Ministry of Public Education.

Costa Rica.—The Department of Health and Hygiene (Departamento de Salubridad e Higiene) of Costa Rica is under the auspices of the Ministry of the Interior and Police.

Ecuador.—Health work in Ecuador is confined to the Sanitary Section (Seccion de Sanidad) under the Ministry of the Interior.

Guatemala.—In this country health is administered by the Superior Board

of Health (Consejo Superior de Sanidad) under the Ministry of Interior and Justice.

Haiti.—The health department of Haiti is styled the Sanitary Service, being a bureau in the Department of Public Works. This bureau is in charge of an American engineer. There is also a medical council which controls certain phases of public health and the practise of medicine and pharmacy. At present, an officer of the Medical Department of the United States Navy acts as chief health officer of the Republic.

Honduras.—The Bureau of Hygiene and Health (Departamento de Higiene y Salubridad) of Honduras is under the auspices of the Ministry of Interior and Justice.

Mexico.—The Superior Board of Health of Mexico is under the auspices of the Ministry of the Interior.

Nicaragua.—The National Department of Health of Nicaragua is constituted a part of the Ministry of the Interior. Each department of the national department is divided into subcommittees corresponding to the states of Nicaragua, an organization similar to conditions which obtain in the United States.

Paraguay.—The health department of Paraguay is called the National Bureau of Hygiene (Departamento Nacional de Higiene).

Panama.—Health activities in Panama are concentrated under a National Board of Hygiene (Junta Nacional de Higiene).

Peru.—In Peru the Administration of Public Health (Direccion de Salubridad Publica) is under the auspices of the Ministry of Development (Fomento). The department has an Institute of Hygiene with bacteriological and chemical departments. There is also a department of military hygiene of the Ministry of War.

Salvador.—Here there is an official Superior Council of Health (Consejo Superior de Salubridad) under the auspices of the Ministry of Interior and Public Works.

Uruguay.—The National Board of Health (Consejo Nacional de Higiene) is under the auspices of the Ministry of the Interior in Uruguay, with the following bureaus: (1) medicine—legal and professional; (2) maritime sanitation; (3) inland sanitation; (4) hygiene of public establishments and foodstuffs; (5) industrial hygiene and collective dwellings; (6) school hygiene and hospital hygiene; and (7) salubrity, drainage, and public works.

Venezuela.—In Venezuela there is an officially constituted Bureau of

National Health (Oficina de Sanidad Nacional) under the auspices of the Ministry of Interior.

United States Organizations

The health activities of the United States government are rather widely scattered, every one of the ten cabinet departments, either directly or indirectly, doing health work. In the Treasury Department is the Public Health Service, which performs the greatest amount of the health work in this country. The Treasury Department also has the Bureau of War Risk Insurance and the Bureau of Internal Revenue, which enforces the Harrison Anti-Narcotic Act, and the medical work of the Bureau of Engraving.

The Children's Bureau, the Women's Bureau, and the Bureau of Labor Statistics are in the Department of Labor. The Department of Agriculture has a number of bureaus which do health work, including the Bureau of Chemistry, which administers the Pure Food Act; Bureau of Animal Industry; Bureau of Entomology; Bureau of Biological Survey; Bureau of Roads, including sanitary engineering; and States Relation Service, which comprises home economics. In the Department of the Interior are the Division of School Hygiene of the Bureau of Education, the Bureau of Mines, Bureau of Indian Affairs, and the Hospital for the Insane and Freedmen's Hospital in the District of Columbia; it also includes the medical activities of the Pension Bureau, and in Alaska. The Bureau of the Census, responsible for vital statistics, is in the Department of Commerce, as is also the Bureau of Standards, under whose auspices is conducted industrial hygiene. The War and Navy Department each has its own Medical Corps. Besides the bureaus in the cabinets there are several independent bureaus,—as the Federal Board of Vocational Education, the Interdepartmental Social Hygiene Board, the Medical Service of the Government Printing Service, and the Interstate Commerce Commission's Bureau of Safety. In all, there are about thirty separate government bureaus which are concerned with some aspect of public health work.

Austria and Hungary each have bureaus of public health. Germany had a highly organized health bureau before the war and probably still has one, though the authors have collected no data on it. China has no really organized health work under public control, though the new government

has cooperated with private agencies. The authors have no information on Bulgaria, Portugal, or Turkey.

Health Work Summarized

Of the seventy countries listed in the Statesman's Year Book for 1920, eleven have really independent Ministries of Health, as follows:—England and Wales, Ireland, Scotland, Canada, France, Czecho-Slovakia, Poland, Kingdom of the Serbs, Croats, and Slovenes, Brazil, Cuba, and Santo Domingo. Of twenty-nine others about which reliable data are available, twenty-one have departments of health under the Ministry of the Interior, two under the Ministry of Education, and one each under the Ministries of Labor, Social Affairs, Public Works, and Development. The public health work of the United States is controlled by ten cabinet officers.

An English Conference on Child Welfare

An English Speaking Conference on Infant Welfare was held in London on July 5, 6, and 7 under the patronage of the Ministry of Health. The main subjects to be discussed are:

- (1) Presidential provision for mothers and babies.
- (2) Inheritance and environment as factors in racial health.
- (3) The supply of milk, its physiological and economic aspects.

Papers were submitted by a number of authorities from all parts of the world. Throughout the Conference a mothercraft exhibition was open from 11 a. m. to 9 p. m., at which the main features consisted of practical demonstrations in important matters relating to infant care. For the benefit of infant welfare workers of all kinds lectures were offered every evening during the Conference on: (1) The ideal maternity and child welfare center. (2) Common infections in mother and child. (3) The tuberculous mother and her infant. (4) The syphilitic mother and her infant. (5) The accessory factors in infant feeding. (6) The psychology of the mother and her child. The need to find in child welfare work the essential social factors has led to many phases of research, both in medicine and economics, which have resulted in health records of enormous value, in districting to serve the whole people through infant welfare and maternity centers, and has aroused a generally awakened interest.

Housing as it Relates to Public Health*

Preserve the Integrity of the Home,
and Give the Children a Place in the Sun

By JOHN MOLITOR, ARCHITECT, CHIEF BUREAU OF HOUSING, PENNSYLVANIA DEPARTMENT OF HEALTH,
HARRISBURG, PA.

IN THE present reconstruction period, nothing is of more importance in safeguarding the public health than housing. Old houses that should be discarded must be used owing to the scarcity and the high cost of new construction.

Houses that must soon be built should be safeguarded by health legislation. We have laws demanding that food, drugs, etc., shall meet minimum specifications, also laws prohibiting short weights and measures being given to the unsuspecting public. It, therefore, seems perfectly natural and necessary that so important a subject as the sanitary equipment of houses and the safeguarding of arrangements for privacy and for the entrance of fresh air and sunlight be subjected to the same kind of intelligent control.

It is a common observation that the tendency of recent years, with the

This apartment building has ten rooms which are without light and air direct from the outside.

great development of industry, has been the concentration of population into cities and towns. With no one responsible for solving their housing problem, what has happened? The overcrowding of land with all sorts and conditions of buildings, and the overcrowding of old houses not adapted to new conditions.

It is to be regretted that an absolute measure of the importance of each housing defect can not be deter-

No proper perspective is possible in matters pertaining to public health without a precise knowledge of how the people live. A study of disease and of the failures in life usually resolves itself largely into a consideration of environmental conditions which the individual is powerless to control.

An abundance of open spaces, plenty of light, and a recognition of the universal necessity for play, along with the development of a sense of civic responsibility for the forces which produce and perpetuate the homeless, yardless tenements, will mark the rise of a better society.

mined; but it is interesting to note in the studies made by the Children's Bureau of the United States Department of Labor on infant mortality in Johnstown, Pa., that in homes where water was piped into the house, the infant mortality rate was 117.8 per thousand, as compared with a rate of 197.9 in homes where the water had to be carried into the house from outdoors—a difference of eighty per thousand; and that in the home of 496 live-born babies where bathtubs were, the infant mortality rate was 72.6, while it was more than double, or 164.8, where there were no tubs.

In dry houses of Johnstown we find the infant mortality rate is 122.5 per thousand, while in damp houses it is 156.7 per thousand. In homes in which there are water closets the rate is 108.3 against a rate of 159.3 for homes that use a yard privy; also homes with clean yards have a rate of 99.9 against a rate of 169.3 for homes with unclean and filthy yards.

The infant mortality rate for the whole city was 134, therefore, in every instance where improved housing conditions existed, the rate was below that of the whole city; while in every instance where the unimproved and bad housing conditions existed the rate was greater than that for the whole city.

Ventilation is another important item that indicates the intimate relation existing between good housing and good health. For we find out of a total of 1,389 babies who lived at least one month, that the infant mortality rate was 87.8 for the whole city; of those who slept in rooms rated as well ventilated, the rate was 28.1; of those who slept in rooms rated as poor, the rate was 169.2—a difference of 140 per thousand.

In preparing for the broadening of housing work which must necessarily come, one of the greatest difficulties we have to contend with is the belief of many people that by reducing yards to as small an area as possible in order to build more houses per acre, they are thereby helping to bring down the cost. Someone must say at what point the building up of land area shall cease in order to permit healthful living.

This tunnel is the only entrance to twelve apartments

Adequate yard areas in relation to dwellings and especially in relation to buildings used for multiple habitation are not wasting land values, but are the conservation of air movement and of the sunlight necessary for healthful living.

In many towns in Pennsylvania we have overcrowding of land area, where people are crowded in a small section of the town. The lots are built upon in the front, center and rear. The interior houses on the lots are reached through narrow passageways or tunnels, hardly three feet

*A talk before the Housing Conference, Philadelphia, May 9, 1921.

When public health has to contend with living conditions like this, it must be considered a losing game.

A chronically poor physical condition, not to mention mental stagnation, must result from the effect of this environment.

wide between buildings. We found from fifteen to twenty children playing in spaces of not more than two or three hundred square feet, completely surrounded by houses and batteries of privy vaults; dismal, dreary courts, without sunshine or proper ventilation.

Why is it that our educational authorities in studying schools over the whole eastern half of the United States remark on the pallid complexion of the school children?

Outsiders in the Home

Those most interested in real estate projects, especially in the construction of small houses, are sincere men, anxious to keep down the cost of small houses, but they are so keenly interested in that phase of the problem that they defeat their own object, for the history of all land development shows that overcrowding invariably produces a rise in land values, forcing rents up so that the small householder must either move out or take lodgers.

Recent investigations of housing conditions throughout the state by the Bureau of Housing reveal the following facts:

(1) Houses and apartments arranged and intended for use by only one family are now housing two or more families.

(2) Conditions of storage warehouses indicates an unparalleled storage of household goods consequent upon the curtailing of family life.

It has been demonstrated that good surroundings pay in the better residence property. Will the housing problem ever be successfully solved until more consideration is given to the creation and permanent safeguarding of neighborhoods of consid-

able area for the man who earns a low wage?

The opening up of yards and areas to furnish open air spaces for the entrance of sunlight and the circulation of air is needed in many old houses as well as the improvement of their sanitation.

Overcrowding of houses means close contact which results in a marked increase in the infant death rate. Infant mortality is much higher in districts where there is the greatest overcrowding. Tuberculosis is more prevalent in overcrowded rooms than where normal conditions of living exist. Approximately from 70 per cent to 80 per cent of tuberculosis cases must live at home as there is not enough institutions to accommo-

date all cases. Overcrowding makes it impossible to adequately segregate a tuberculosis patient. All communicable diseases, especially influenza and pneumonia, are rapidly spread by overcrowding and the difficulty of maintaining adequate quarantine or isolation of cases in tenement houses.

Where Tuberculosis Occurs

Tuberculosis is a disease which in the majority of cases occurs in houses or apartments of three rooms and under; the number of cases are larger in two room apartments than in three, is larger in apartments of one room than in two; and also the number of cases of tuberculosis and pneumonia increases almost in direct proportion to the number of overcrowded houses or apartments in any district or ward of a city.

If these facts regarding the influence of housing on the origin and spread of tuberculosis be correct, then something more sweeping in the line of preventive work must be done, than has yet been accomplished.

Patients who have been discharged from sanatoriums as cured, must not return to the same living conditions under which they formerly lived when they contracted the disease.

Tuberculosis, pneumonia, and practically all the infectious diseases are not only more prevalent in the crowded dwelling and apartment, but are more apt to be fatal. The infant mortality rate is correspondingly higher.

The studies and conclusions of Dr. Chalmers, Health Officer of Glasgow, if we use infant mortality as an index and indicate the death rate of infants in one room apartments by the figure 100, that the two, three, and four room apartments would be indicated

When gardens grow on spots like this, many public health questions will fall largely into the background.

Can schools make good citizens of children who spend most of their time among these sordid scenes

The problems of the future are inextricably bound up with the housing conditions of the present

by an index of 78, 61 and 49; in other words, the child born in the one room apartment has only half as good a chance for its life as one born in an apartment of four rooms or larger.

It not only happens that the infant death rate, that is of children under one year, is greatly increased in the one room apartment, but it is perhaps equally true that those who escape death are physically handicapped so that in the next period, that is between the first and the fifth year, they are much more likely to be sacrificed to other diseases. These facts are clearly brought out by the statistics of Dr. Chalmers, who shows that between the ages of one and five, the death rate per one thousand for one room apartments is 16.6, for two room apartments only 12.6 and for three room apartments 7.2, for four room apartments and upwards 3.1 per one thousand.

Good housing conditions for health, comfort and good citizenship in apartments, well lighted, ventilated and with sanitary conveniences arranged with due regard for family life; are the right of every family.

Vision and imagination are needed to understand the vast possibilities in multiform housing, and of the civilizing effect on people which will come by providing them with livable and economical homes. We must fight against ignorance and inertia.

Children very early in life are susceptible to public health education, and if the elementary foundations of sanitary conscience are well laid in the schools, these pupils when fully grown will be the sanitary educators of the next generation.

Weakened bodies indicate a large economic waste. This waste, mainly attributed to poor housing conditions, is quite in line with our great national waste of natural resources, our forest and city fires and our disregard for the future. As an organized and effective conservation is the only

answer to the great wastes of our industrial population, which is the source of the country's real strength. We must be inspired to make possible the right for healthful living; we must recognize the need as economic; we must appreciate the ineffectiveness of our elaborate school system in making good citizens when the housing conditions in which the children live are diametrically opposed to it.

With good housing you will be assisting in establishing elements of personal character, of industry, and of cooperation and enterprise that are essential to a progressive and enlightened citizenship. You will be developing a new patriotism, not tragic as that found upon the field of battle, but more essential than the other in attacking the great industrial, social, and economic problems of the future. To just that extent that we enter into the modern spirit of community promotion, welfare and safety, to just that extent we are lending our efforts, our industry and our lives in building up a new national as well as local life.

The infant mortality of children who slept in rooms rated as well ventilated was 28.1, as against 87.8 for the city as a whole. Ventilate the bedroom.

New York Nutrition Council Reports

The New York Nutrition Council, consisting of representative members from approximately one hundred different organizations, has after twelve sessions reported on the correlation of nutrition activities, and on training standards for nutrition workers. Copies of the recommendations covered by this report may be obtained from Emma A. Winslow, secretary, New York Nutrition Council, 105 East Twenty-second Street, New York City.

The Committee defines the relationship between nutrition work and adequate medical service, and emphasizes the necessity of parallel educational work reaching both children and adults, and of adequate social work for the diagnosis and treatment of social causes for malnutrition.

The requirements of the situation brought out the needs for extensive study in several directions which is to be undertaken during the ensuing year, at the end of which time their completed report on the problems of correlation will be compiled.

Practical Preventive Medicine

Dr. Mark F. Boyd, professor of bacteriology and preventive medicine in the Medical Department of the University of Texas, has brought out a book on practical preventive medicine which includes all of the most essential facts of this subject. These facts are clearly stated, the book is well arranged, and constitutes a highly satisfactory introduction to the subject.

W. B. Saunders Company, 1920.

To raise the level of national health is one of the surest ways of raising the level of national happiness. No branch of legislation is more really valuable than that which is occupied with the health of the people.—Lecky.

Economic Problems in European Health

BY C.-E. A. WINSLOW, YALE UNIVERSITY, DIRECTOR, DEPARTMENT OF HEALTH, THE LEAGUE OF RED CROSS SOCIETIES, GENEVA, SWITZERLAND

EVEN in favored America we rightly attribute a considerable importance to economic forces as factors in the determination of the death rate, but one must study at first hand the present health problems of eastern and central Europe, in order to realize fully how overwhelmingly important such economic factors may become.

Typhus fever, for example, is in theory—and, in practice, where resources are ample—an easily controllable disease. Yet Poland is still suffering from a serious epidemic of this ancient pestilence. The Epidemic Commissariat of Poland, with the aid of the Epidemic Commission of the League of Nations, is making a magnificent fight against it. The energy and efficiency shown by the Poles in rebuilding the public health machine destroyed by the Bolsheviks last fall might be a source of pride to any nation in the world. One hundred seventeen epidemic hospitals and 353 field disinfecting columns are already in operation, and admirable quarantine stations have been equipped for the cleansing of the prisoners and refugees now streaming back from Russia. The epidemic is on the wane. Reported cases in January, 1921, were 78 per cent less than in January, 1920. They were 4000 per cent higher, however, than the average for the corresponding month and corresponding areas before the war; and relapsing fever is far more prevalent than typhus. Salvarsan, with which relapsing fever could be easily stamped out, is so costly that only the larger hospitals can be supplied with it. The fundamental habits of personal cleanliness, which alone will serve for the complete eradication of the louse-borne diseases, are quite out of the question in the villages where seven years of war have destroyed the bath houses, where soap is impossible to obtain, and where even firewood for heating water is often lacking. The Hebrew Joint Distribution Committee under the direction of Dr. Plotz, is engaged on an excellent plan of constructive work in the upbuilding of village sanitation in Poland; but the construction of baths and the provision of soap and fuel are the vital economic essentials which must underlie any plan of health propaganda.

In Austria, the influence of economic conditions upon health has been even more overwhelming. In 1912 the city of Vienna had 39,801 births and 32,141 deaths, an excess of 7,660 births. In 1918 there were 19,257 births and 51,497 deaths, an excess of 32,240 deaths. This was, of course, both a war year and an influenza year. In 1919, however, there were still only 24,347 births against 40,932 deaths, an excess of 16,585 deaths, and this condition was almost wholly the result of diseases directly and indirectly due to malnutrition and privation.

Recovery from such a condition is exceedingly difficult. The present Austrian state can produce food only for one-fourth of its population. Its industrial life is hampered at every turn by new political boundary lines which cut straight across the natural paths of trade. The crown has fallen to an appallingly low level. The income of the most fortunate Viennese has only quadrupled while the cost of living has risen one hundred and fifty fold.

There are signs of hope, however, even in Austria. Coal is beginning to come in from Czecho-Slovakia; and unemployment has substantially decreased. The feeding work of the A. R. A. which is being carried out under the direction of von Pirquet, according to his exceedingly interesting "Nem" system, the Child Welfare activities of the Society of Friends, and the multifarious services of the American Red Cross, are beginning to bear fruit. The birth rate is rising in Vienna and the death rate falling, although still showing a net loss of population.

The Austrian situation is not hopeless; but it represents by far the most critical problem of post-war reconstruction which the world must face. It is in very truth a world problem, rather than a purely Austrian problem. There is at stake here, not merely the lives of individuals, but the life of a civilization. Vienna as a center of art and music, of medicine and science, of philosophy and letters, Vienna as the embodiment of a truly rich and warm and liberal culture, stands with Paris as one of the precious flowers of human civilization. Its decay would be an irreparable loss to all mankind. It is to the preser-

vation of this culture, which it has taken centuries to produce, as well as for the immediate mitigation of human suffering, that the best sanitary knowledge and the clearest economic foresight and the fullest generosity of the world must be applied.

Public Health Women Meet

With members in twenty-nine states, including twelve Federal employees, the Association of Women in Public Health held its annual meeting in Boston under date of June 6.

Miss Gertrude Seymour, correspondent of the Federal Public Health Service, presided at a business session for members. Roll call showed members from Maine, New Hampshire, New York, Pennsylvania, Washington, Illinois and Michigan as well as a large representative from the Massachusetts State Board of Health. Dr. Carro C. Croff, lecturer of the New York State Department of Health, reported for the membership committee and Miss Marjorie Delavan of Michigan for the Bulletin, which has served to introduce the Association and which, she said, will be strengthened and enlarged in the coming year.

Dr. Rachelle S. Yarros of Illinois spoke of the value of establishing institutes and classes with the cooperation of boards of health and women's associations, for the purpose of discovering persons qualified for leadership in public health matters.

It was voted to change the date of the annual meeting from December to June, and thus be in line with the American Medical Association convention. Dr. Mary Riggs Noble of Pennsylvania, treasurer of the Association, submitted an outline of a budget for next year, but this matter was laid aside until the late afternoon by unanimous consent.

Miss Seymonth was re-elected president to serve with the following named officers:

Vice-president, Rachelle S. Yarros, M.D., Illinois State Department of Health; treasurer, Mary Riggs Noble, M.D., Pennsylvania State Department of Health; secretary, Mary R. Lake-man, M.D., Massachusetts Department of Health.

Practical Experiments in Seating in Industry*

An Ounce of Intelligent Experimentation Is Worth a Pound of Abstract Argument

BY EDITH HILLES, BUREAU OF WOMEN IN INDUSTRY, NEW YORK STATE INDUSTRIAL COMMISSION, NEW YORK CITY

A TRIP through an average plant is almost sure to disclose startling novelties in the way of seating arrangements. All seats may seem to look more or less alike until

Fig. 1. This shows a makeshift method which has been used to raise the height of a chair.

attention is directed towards them, but then behold the possible varieties! Twenty different kinds of chairs may be gathered together from the same plant; no one of them a really satisfactory seat. They have been purchased at different times by different people for use at different processes, but the only considerations have in all probability been cheapness, durability, and free aisle space. As a result, in many cases improvements have been attempted by the workers: backs have been knocked off or put on; chair arms or cushions have been added; a box or a barrel has been made into a seat; a chair seat has been raised by some such makeshift method as that illustrated in Figure 1, or an ingenious workman has built out a seat from a part of his machine. One industrial engineer has well said that, in his experience, it is wise to

watch very carefully for indications of such adjustments on the part of the workers and that "when stools are found with boards nailed on to provide a crude support for the back; when old boxes or broken chairs are being used under the benches for foot rests, we may be certain that the plant is not being operated at a maximum of physiological efficiency."

The difficulty seems to be not only that very little thought has been given the question of industrial posture, but also, that in most cases it is impossible to scrap old equipment which has been constructed with no regard for the breaking back or the dangling legs of a tired workman. However, it is fortunately coming to be true that "manufacturers who employ large numbers of workmen are slowly discovering that it pays in dollars and cents to study the postural needs of their employees, and to provide for them an environment suited to their needs."¹

Nothing is more fascinating than the ingenious methods which have been employed to improve the still too common workplace which is badly lighted, with benches or machines either too high or too low, and, if seats are supplied at all, they consist of kitchen chairs or round top stools in varying stages of dilapidation.

Foot Rests a Problem

The problem of proper foot rests has resulted in interesting experiments. Figure 2 shows an excellent foot rest which can be adjusted at an angle and also at a height to suit the individual worker. The end fittings are made of cast iron and the foot rest itself is made of wood. This wooden part is attached to the metal ends by the use of wood screws and a flange on the bottom edge of the swinging hanger. In Figure 3, the brace interferes with the ordinary type of good foot rest and also with knee space. The narrow bar which

Fig. 2. An excellent type of foot rest, which can be adjusted as to height and angle to suit the individual worker.

*The third of a series of articles on the relation of posture to industrial health compiled from the data contained in the reports of the Bureau of Women in Industry of the New York Industrial Commission on Industrial Posture and Seating. The illustrations used are from those furnished this Bureau for their report.

1. Mosher, Eliza M.: *Relation of Posture to Health*, American Posture League, New York, 1917, p. 5.

is used here, and which can be adjusted in height, is bad, but there is no reason why a broad flat foot rest could not be used with such a bar as a foundation. The seat in this instance should be lower so that the knees need not be so crowded.

Fig. 3. Here the brace interferes with the ordinary type of good foot rest and also with knee space.

The question of pedal work has aroused much discussion and has proved so fatiguing in many instances, that women are discouraged from certain types of pedal work. A large manufacturing concern writes that "the old, round stools with saucer shape seats cannot be too strongly condemned. We have known of cases of semi-paralysis of the leg muscles due entirely to sitting on such stools and operating foot treadles in connection with machine operations."

Where much pressure is necessary, seating arrangements should be planned with particular care in order to eliminate as much strain as possible. The seat in Figure 4, while better than no seat at all, is too small to be satisfactory and is of a shape which cannot give the needed support. It is also stationery, whereas it would be greatly improved if the distance from the presser could be adjusted to suit the individual worker. Figure 5 shows a new type of foot pedal where a forward and backward knee movement replaces the old type where ankle action and a certain amount of pressure were required. The operation of this foot pedal is very restful. There is no up and down movement as the whole pedal swings backward and forward with a slight push of the foot. The backward and forward excursion of the pedal is approximately

six inches; the pedal is based on a table or machine which is almost thirty inches from the floor. The main pivot point of the pedal is approximately three inches above the chair upon which the operator sits, and this is the base measurement from which all other measurements are obtained. The height of the pedal from the floor is adjustable by raising it to a higher hole in the two parallel arms which support it. A cleat of wood running across the pedal serves to brace the heel so that no effort is required to keep the foot in place. The tilt of the front end of the pedal is adjustable, so that the angle can be suited to the operator. The picture shows the left pedal tilted up and the right pedal flat. This foot pedal may be applied to any machine or table where a vertical, horizontal or angular movement is required. Any desired movement may be obtained from one to eight inches in any direction. The movement desired to perform an operation is obtained by a suitable foot rest horizontal to floor, a pair of parallel arms at right angles to floor and such levers or arms as may be best to give desired results. This picture shows a stem machine used in making electric light bulbs. Two separate pedal operations are required, and the two pedals shown can be operated independently of each other. In machines requiring only

one pedal operation, one pedal is used and is placed in the center so that the operator can work it with first one foot and then with the other.

Figures 6, 7, 8a and 8b, 10, and 12 illustrate experiments for ironers. A man or woman who operates an ironer or does hand pressing, is commonly supposed to stand, while at work. The result is that such workers have constant trouble with their feet and are often exhausted at the end of the day. There is no reason why arrangements can not be made whereby they can be seated for part of the time, and do better work as a result of this chance to vary their position.

Figures 10 and 12 illustrate machines advertised as particularly desirable, because the operators can be seated at work. Figure 6 is a simple arrangement for pressers by the use of good chair adjusted to the pressing board.

Figure 7 shows a unique presser's bench used for light work on children's garments. The operator stands between the movable ironing board and seat. The seat is stationery and tilted forward. When seated, the operator does not lean against seat, but sits on it with the ironing board pulled toward her. Her feet rest on the floor. For a short operator, a foot rest should be provided. The height of the ironing board from the

Fig. 4. An unsatisfactory seat, requiring that distance from presser be adjusted to suit the individual worker.

Fig. 5. Shows a new type of foot pedal where a forward and backward knee movement replaces the old type where ankle action and a certain amount of pressure were required.

floor is $31\frac{3}{4}$ inches; the front edge of the seat is $28\frac{3}{4}$ inches from floor; the back edge of the seat is $30\frac{1}{2}$ inches from floor; and the width of the seat is $8\frac{3}{4}$ inches. The ironing board is one and one-half inches thick and has a piece of wood nailed to either end under side so that it slides along as if on a track or can be pushed off to let operator in or out.

Sliding seats have developed in some instances in connection with work where the operator had to stand and move from one end of the machine to the other, or where several machines were tended by the same person. Figures 8a and 8b illustrate a type of sliding seat used for a girl operating a collar ironer. The foot rest, although a bad shape, is adjustable in height, and the supply box is at a good height and angle. The track is 36 inches long. The seat and track swing out of the way so that the girl can stand when she wishes. (Figure 8a.)

On page 340 of the June issue of *THE NATION'S HEALTH* is shown another type of sliding seat used for a girl operating two collar ironers. Here the operator reaches down in the supply box at the right to get collars and feeds them into the first ironer. By pushing on the foot rest with her feet she slides the chair to the second ironer. When this is filled,

she gives a vigorous push with her feet and also with her hand on the edge of the ironer, and in this way is again in the starting position. This long slide back makes the operation a quick one, but pushing at this angle with the support of an arm rest to steady the box may be a bad strain on the operator. The wheels are ball bearing and the chair moves very easily. Note the low, bad position of the supply box at the extreme right. The track is supported at both ends and in the middle by uprights of lead pipe. Through holes in the top of these pipes other pieces of pipe fit at right angles and are fastened in place by pins. The track is fastened to these horizontal pieces of pipe and both track and horizontal pipe supports can be slid back out of the way when the operator wishes to work standing.

Figure 14 shows still another type of sliding seat designed so that workers can tend four automatic machines placed one foot apart. The track is composed of two rails: inner one convex, outer flat, $16\frac{1}{2}$ inches apart. The chair is fastened on a 21-inch square metal platform, the center of which has been removed to lessen weight. Ball-bearing wheels are attached to under surface of platform. Two treadles are attached to each machine, one to start the machine, one to release work. By pressing the

foot against "release" treadle, the operator receives the impetus to move chair along track. The total length of the track allowed each operator is 145 inches.

There is a difference of opinion as to the wisdom of encouraging the use of sliding seats on tracks by women because of the necessity for a constant pushing motion. Such seats should be most carefully constructed to give steady support to the worker's body.

Figure 11 shows a unique type of seat which swings rather than slides. It is used in Sheffield, England, in front of a tilt hammer. The height of the seat from the floor can be adjusted by the hook in the loops of the chair.

Posture Being Studied

Companies manufacturing machinery and installing it are more and more taking into account the posture of the worker. A large firm writes: "We have installed quantities of machinery, not only in the canning industry, but in other factories and we have at all times been very careful to take into consideration the height at which it is most comfortable for the operator efficiently to perform his or her duties and we find that a distance of approximately 30 to 32 inches from the floor to the top of the table is usually the one most desired."

Figure 13 illustrates a highly ad-

Fig. 6. A high chair which enables the worker to sit or stand at work greatly reduces the fatigue.

justable type of seat built with a tobacco stripping machine. The seat is adjustable in three respects: the distance from the machine, by means of a hollow tube that slides over the rod at A; position of the back which may be folded over the seat at B; height of seat, C. The chair folds up at three points so that it may be put out of the sweeper's way. When folded, the chair prevents the treadle moving. In one factory where this machine was used a larger wooden seat had been placed over the original one. The chair is heavily built and wears well. In a factory where it had been used for a number of years it was still not in the least loose or wobbly, in spite of the many adjustable features.

Figure 9 illustrates an experimental first-step in working out a good seat. At this process, work must be done leaning forward and the ordinary kitchen chair supplied in the plant proved to give no back support. Straight boards were nailed to the chairs in an attempt to secure this needed support, and the company are trying by different experiments to work out the best type of seat for this particular process.

In the summer of 1920, 103 of the largest firms in the New York State reported to the Bureau of Women in Industry on their seating arrangements.

Fifty-nine of the firms were using "ordinary chairs with backs," throughout their factories. Stools, apparently without backs, were still in use in some twenty-five of the plants.

These reports were significant in that the necessity for varied posture had apparently received much more attention than the necessity for a properly constructed seat. In fourteen cases it was specifically mentioned that supplies were purposely regulated in such a way as to make it necessary for those who were seated

at work to rise and change their positions in order to remove the finished goods and secure new materials.

It was also interesting that eleven times the firms reported that "since the work is piece work, the operators can rest and change their positions whenever they wish"; that they *can* when on piece-work is true; but whether they *do* is quite another

story. Fifteen of the firms reported a regular system of rest periods, in one case for the "office workers only." In five cases the rests were "automatic," due to the nature of the process.

It is surprising that among these firms only five instances were found where seats were adjustable in any way. Eleven other firms were using seats built in different heights, but foot rests had been considered by only four of the 103 plants.

As has been suggested, the incentive for considering what good posture is and how to provide for it may have come from industrial engineers, or from a humanitarian interest on the part of the management, or it may have come from the workers themselves through unions or representatives of employees' organizations or through individual workmen. An interesting case is that of a hosiery mill where the workers in one department formally submitted a request that chairs be used in place of stools. They

Fig. 7. Without adjustment of workplace to worker, the monotonous process of ironing becomes unduly fatiguing. A unique presser's bench for light work.

Fig. 8a. This seat swings back out of the way when the operator desires to stand.

Fig. 8b. A type of sliding seat designed for a girl operating a collar ironer.

gave three reasons for making this request:

"We can do better work.

"We can increase our production.

"We can go home at the end of the day without pains in our backs and the possibility of being absent the next morning from work because of a headache from the constant strain of leaning over our machine all day with no chance of relaxation."

While many times workmen have suggested improvements, on the other hand, it is often very difficult to persuade them, particularly if they are on piece-work, to try a position which means a change from the accustomed way in which speed has been attained. Motion study experts have found great difficulty in persuading workers to accept changes in motions or in the designs of work benches, or in persuading old-time workers to sit at an operation that has been carried on for years in a standing position. The practice of teaching apprentices in regular vestibule schools has done much to overcome this difficulty. The apprentice can then become accustomed to performing an operation either sitting or standing, and has a chance to learn what a good seat is and how to use it correctly.

An Economic Motive

The economic motive has prompted most industrial engineers to plan for postural needs, because of their desire to increase production. The figures of "before and after" condi-

tions tell a long story and would indicate that careful consideration to the so-called fatigue "trifles" in industry may make these trifles milestones in production possibilities.

Letters came to the New York State Industrial Commission during their study of Industrial Posture from firms all over the country, and the statements of these firms, containing both good and bad points, are extremely significant in furnishing us with definite information as to what experiments are actually being made. The following are examples:

Firm No. 1—Paper Goods—writes:

There are two or three outstanding features which we feel are very important in the construction of a chair for factory purposes. First, the usual chair has too deep a seat from front to back so that the workers do not sit back far enough on the chair to receive the benefit of the back. You will note from our chair that this dimension has been decreased to thirteen inches. You will also note that there is a downward slant toward the back of three-fourths of an inch between the back of the chair and front of the chair which gives a quite natural tendency to cause the workers to use the back which is the prime object in view.

The back is adjustable both in and out, and up and down, and the chair itself is adjustable up and down to accommodate the different workers to a standard height table.

The feet are taken care of by an adjustable foot rest.

It is possible to adapt our chairs to a multitude of uses by having legs of different lengths made up. We are using some with shortened legs made up. We are using some with shortened legs, on sewing machines, and some with very much longer than regular legs for high machinery, and also for use at standing benches, particularly in our drafting room.

Firm No. 2, manufacturers of electrical supplies, make this report:

We are intensely interested and have been for some time on this question of proper chairs for industrial workers and we are trying hard to find a type best suited for our workers.

We have worked out very satisfactory foot rests of the adjustable type and a very efficient foot pedal which has eliminated all fatigue resulting from the use of our old type where the ankle had to do the work.

From firm No. 3, makers of paper boxes, comes this comment:

Fig. 9. This represents an experimental first step in working out a good seat for a process which requires the worker to lean forward.

Fig. 10. A type of machine designed with especial consideration for the worker.

We have made a number of different kinds of stools with the idea of making our workers as comfortable at their work as possible, and have found the main consideration to be a height suiting the particular operation, a back which need not be used at all times, but can be used in case of slight fatigue, and a foot rest made adjustable so as to suit the operator . . . we have made some of these stools in our carpenter shop. . . .

The following account is given by firm No. 4, makers of clothing:

Some of the points we have considered in selecting seats are the following: (1) A broad seat capable of holding a person of any size. (2) Seat should be slightly concave. (3) The slope of the seat. (4) A sloping back slightly curved and not too straight. Straightness of the back, by the way, may vary with the nature of the operation. (5) Chair should have one or two rungs at the front and sides on which to catch the heels. (6) Strength of chairs. (7) Price.

We have also found that a round top chair is impossible, because of the active discomfort it occasions the operator. Further, that stools without backs are not to be considered.

Firm No. 5—camera supplies—has made the following deductions:

The essentials of proper seating, in our judgment, are as follows:

(1) That chairs be adjustable to the height of the employee and adjustment provision be made for tilting the chair seat at an angle to conform with the class of work done.

(2) That the chair seat be form fitting similar to the very familiar mowing machine seat, although not as much so.

(3) Chairs should be provided with adjustable back rests which will support the operator in the hollow of the back and which are form fitting so that they support the operator against side movement. In other words, they should be curved out so that they will go around the operator's body a little on either side. Then, too, these back rests should not be rigid but should be provided with springs so that they will be flexible and yet exert a helpful moderate pressure against the operator's body.

Of course, operators should be so seated when at work table that their arms are practically horizontal. In one of our departments we provided

stools similar to counter stools used in dry goods stores, these being rigidly fastened to the floor and provided with a spring which threw the chair up close to the machine when not operated by the operator. This was in one of our dark rooms where it was very important to keep the aisles clear in case of fire drill or any emergency. In our judgment, however, these were not as good as the chairs mentioned above.

Most of these attempts are obviously compromises between what has been and what might be. There are no absolute standards. The best we can do is to follow a few fundamental principles of good posture and refuse to accept, with no regard for physical needs, what custom has

Fig. 11. A unique type of seat which swings rather than slides. It is used in Sheffield, England, in front of a tilt hammer.

chanced to give us. Must a worker always endure a bench constructed too high or too low? Must a clerk always use the conventionally bad desk chair? Must a housewife always accept the plumber's insistence that the kitchen sink and washtubs be built at a back-breaking height?

To take some slight step in the

right direction is usually so simple that it seems foolish to suggest it, but some step, however simple, is that much better than no step at all and eventually we may be able to have chair companies manufacture "a seat that never wears the worker out" rather than "a seat that never wears out."

Accidents in the United States

By MYRA HULST, AMERICAN RED CROSS, WASHINGTON, D. C.

ACCIDENTS killed more people in the United States during 1918 than the much dreaded disease, cancer. The toll of accident deaths was more than 83,000 in the one year, 1918. The control of accident fatalities and disabilities is one of the outstanding problems in the movement for longer and healthier lives in America.

The accompanying table reveals the extent of the accident deaths by cause in the United States.

Automobile deaths have increased tenfold during the past decade. Ninety people out of each million were killed by automobiles in 1918 as compared with ten per million from 1906-1910. While the safety movement in America has succeeded in reducing railroad and street car accidents to a considerable extent, automobile accidents have been allowed to increase at this appalling rate.

Life saving in which the Red Cross has had a very prominent part in the

past seven years has helped to materially lessen drowning accidents. If the drowning death rate of 1906-1910 had prevailed in 1918, there would have been 2,100 more deaths than actually occurred.

Accident deaths constituted 4.6 per cent of the deaths from all causes in the United States in 1918.

DISTRIBUTION OF ACCIDENT DEATHS IN THE UNITED STATES, 1918

Based on Data from Mortality Statistics. Bureau of Census.

Cause of Accident	Number	Per cent
Total accident deaths.....	83,852	100.0
Poison	2,787	3.3
Conflagration	1,799	2.1
Burns	8,418	10.0
Absorption of deleterious gases	4,247	5.1
Drowning	6,952	8.3
Firearms	2,561	3.1
Falls	13,070	15.6
Mining and quarrying	3,293	3.9
Machinery	3,002	3.6
Railroad and street car	13,762	16.4
Automobile	9,445	11.3
Other vehicles	2,797	3.3
Other accidents	11,719	14.0

Camp for Vocational Trainees

Announcement is made from the main office in Chicago of the Wisconsin-Illinois-Michigan District of the Federal Board for Vocational Education of a summer vacation camp to be held at Fort Sheridan, Ill., June 15 to September 15, 1921, to which are invited all men now in training under the Federal Board for Vocational Education. It is believed that a great many men who could and should receive assistance from the Chicago office are not doing so because they have not been apprised of its possibilities as pertaining to their individual cases.

It is intended that the summer camp shall provide a real vacation for the boys in training, many of whom would otherwise be deprived of one. Information is available on application to Charles W. Sylvester, district vocational officer, Federal Board for Vocational Education, Chicago.

Child Hygiene Association Meeting

The Twelfth Annual Meeting of the American Child Hygiene Association will be held in New Haven, Conn., November 2-5, 1921.

Diphtheria Death Rate in Michigan

Michigan had the highest death rate from diphtheria of any state in the Union in 1918, a rate twice as high as the average for the United States, according to the *Health Bulletin* of the Michigan Department of Health of May 23, 1921. The average rate in the southern portion in 1920 was 26.8 per 100,000; in central Michigan, 19.8; northern Michigan, 18; and for the Upper Peninsula, 10.5. The average death rate for the state increased from 21 per 100,000 living persons in 1919 to 24.1 in 1920.

Census of Chicago Boys

A survey made by the Boy's Club by the Chicago Council of Social Agencies at the request of the Chicago Rotary Club reports that about one-sixth of the boys of the city are reached by agencies of any sort dealing with the supervision of the leisure occupation of boys. In the South Side district there were from nine to ten thousand boys between ten and twenty years of age. Of these, about 737 were reached. Records of the Juvenile Courts show that in districts where boy's clubs work has been organized with adequate equipment, delinquency has been greatly decreased.

Chicago's Health Department

OF ALL the cities in the world, Chicago possesses a unique history in its remarkable evolution in the short space of ninety years from a trading fort to one of the world's greatest cities, and from a swamp to the world's healthiest large city. The achievement of this health record has been achieved by persistent effort—has set a standard which affords an incentive to hundreds of other towns and cities in many parts of the world.

The site of Chicago, in 1673, possessed no indication of metropolitan destiny. A small river offered to the canoes of the Indians and French explorers a convenient harbor and access by a short portage to the larger waters of the Illinois and Mississippi Rivers. The important fact is that there was established at that time a life stream of transportation extending from Montreal to New Orleans, down which there proceeded uninterruptedly continuous travel of the most adventurous spirits of the age. Chicago was then, as now, the center of transportation routes in America.

In the consideration of Chicago's health evolution, it is interesting to record that the first case of sickness was that of Father Marquette who, on December 4, 1674, was obliged to spend a winter on the Chicago River on account of a severe illness. For more than a hundred years, Chicago's importance was measured only by the convenience it afforded for general trading between the whites and the Indians. The Indians, by treaty in 1795, ceded the first six-mile square tract at the mouth of the Chicago River.

Early Housing Problems

The establishment of Fort Dearborn in 1804 brought a measure of stability which resulted in the gradual centering of settlers near the Fort and within easy traveling distance of it in the surrounding country. Nevertheless, the young village offered no allurements according to the report of Major Long, who in passing through Chicago in 1823 and making his first report on housing conditions says: "The village presents no pleasing prospects. It contains but few huts. Their log and bark houses are low, filthy, and disgusting, displaying not the least bit of comfort."

In 1820, the town of Chicago was surveyed and a definite attempt was made to organize its citizens into a

semblance of civic strength. The health conditions were bad. Malarial fevers, cholera, smallpox, and typhoid fever vied with one another in making the lives of the inhabitants miserable and precarious.

In 1835, a board of health consisting of seven members was established. The first cemeteries were set apart, and the first sanitary engineer, Anson

town contained 398 dwellings and was served by three drug stores.

Prior to 1838, the water supply was from wells and by water cart distribution of lake water. This water supply was full of impurities owing to faulty soil conditions, and the mortality from cholera and scarlet fever was very high. It was not until 1840 that the Chicago Hydraulic

The liberation of a people, otherwise city-bound, is effected by means of numerous and conveniently placed parks and playgrounds

Sweet, who was bold enough to construct a plank sewer on Dearborn Street from Lake Street to the river, was severely censured for his reckless expenditure of public money.

In 1837, Chicago graduated by incorporation to the dignity of a city, and the first Code of Ordinances was the first book published in Chicago, fourteen paragraphs being devoted to health matters. At this time the population of Chicago was 4,170, the

Company began to distribute water through bored logs, laid underground. The supply of water was derived from the lake by means of an iron pipe, extending one hundred and fifty feet. A twenty-five horse-power steam engine pumped the water into a reservoir located on the corner of Lake Street and Michigan Avenue.

The chief trouble with the growing city was the low ground on which it was located, and the fight for public

One of Chicago's small parks, which invites life in the open during the whole season

This swimming pool is in one of the smaller parks and provides a healthful sport in the heart of a factory district

Chicago's North Side is served by several beaches. This view of Clarendon Beach represents a typical scene.

health was a losing one, made additionally difficult by the rapid increase of population consequent upon the opening of navigation on the Illinois and Michigan drainage canal, and the operation of the first railroad, in 1848, and the arrival of the Michigan Southern and Michigan Central railroads in 1852.

Some conception of the insanitary condition of Chicago at that time may be gained by a statement of sanitary affairs in 1850. This announced the reappearance of cholera in July of that year. From July 18th to August 31st, 416 people succumbed to the disease. Sewerage system was primitive, and in many streets there were only gutters, serving as drains. In the business sections the sewers were made of heavy oak planks, triangular in shape and placed in the center of the street. The streets were planked: the gutters often clogged, leaving pools of foul liquid in the street, resulting in an intolerable condition for a city which boasted a population of 28,269 people.

In 1860, sanitation received a severe setback by the abolition of the Board of Health and the discontinuance of the offices of health officer and city physician on account of existing financial depression, and the absence of any alarming conditions. As usual, citizens forgot that, if vigilance is not constantly exercised, alarming conditions are bound to ensue. During the Civil War, insanitary conditions increased, and the location of Camp Douglas at Chicago, where 30,000 soldiers were mustered into service, was an additional menace to the city's health. In 1864, the mortality from smallpox was fearful. An attempt to focus the minds of the citizens in health matters was made

by means of a sanitary exhibition which was held in the fall of 1863. Where men fail to do their duty, the remedy is often taken out of their hands, and the Chicago fire of October 8 and 9, 1871, may be regarded as a much needed, though drastic remedy, destroying 18,000 buildings and rendering 93,000 persons homeless.

The recurrence of cholera in 1873 and 1874 lead to the establishment of the Department of Health, and Chicago engaged in a careful study of its sanitary needs, smallpox being the chief factor of menace for a number of years.

Chicago began to build itself anew and raised the level of the city from 8 to 14 feet, making it possible to install an effective sewer system along approved lines.

Engineering Efforts Effectual

The year of the World's Fair stimulated investigation of all buildings throughout the city. The work on the new drainage canal had commenced, and in 1900 it was opened to the immediate advantage of the citizens of Chicago, by effective removal of sewage, and the cleaning up of the lake front.

Since that time Chicago's advance along sanitary lines has been constant and extensive, and is now known as the healthiest large city in the world.

Chicago now possesses a great system of public parks and playgrounds, boulevards, bathing beaches, and forest preserves, unequalled in area, number, variety, and charm anywhere in the world. There are 207 large and small parks, forty-five of which contain well equipped playgrounds, seventy special municipal playgrounds, twelve public bathing beaches and a number of swimming pools and nata-

toriums. More than forty thousand people take advantage of these breathing spots annually. The city is surrounded by a wonderful band of forest preserves exceeding 17,000 acres in extent, all of them easily accessible by street car, electric, or suburban train.

Chicago's present water supply stations can distribute 240 gallons of water daily to every resident in the city, and this amount can be raised to three hundred gallons daily in case of emergency.

The chief factors in the health conservation of Chicago are the purity of its water supply, its abundance of distribution and use, its unique drainage system, and the many opportunities for outdoor sports and recreation provided by its parks and playgrounds, forest preserves, and bathing beaches. All these activities for public good are actively reinforced by the cooperating leadership of well organized Departments of Health and Sanitation, and a fully aroused sense of civic responsibility.

National Tuberculosis Association Meets

The annual meeting of the National Tuberculosis Association was held at the Waldorf Astoria in New York, June 14, 15, 16, and 17, in conjunction with the American Sanatorium Association. A symposium was offered on the Federal provision for tuberculous ex-service men, at which Dr. Haven Emerson and others read papers. The sociological section covered the question of nutrition and the school as a means of approach. A section was devoted to industrial nursing. It was emphasized anew that an adequate tuberculosis service involves a complete public health program.

Leadership of the American Medical Association

THE choice of Dr. George E. de Schweinitz, professor of ophthalmology of the University of Pennsylvania, as president-elect of the American Medical Association places the leadership in the hands of a man whose scientific achievements have long been a stimulus to his profession, and whose specialty has received constant emphasis, both through his contributions to scientific literature and through his social affiliations, in its relations to public health and general welfare. His contributions on subjects which bring out the need of special measures for the semi-sighted are quite as significant as his numerous monographs on ophthalmologic and neurological subjects. Under his leadership the broader phases of medical service as well as scientific research should receive a new stimulus.

Industrial Physicians and Surgeons Meet in Boston

THE annual conference of the American Association of Industrial Physicians and Surgeons held in Boston marked a new advance. The attendance was the best in the experience of the organization. The program crowded five sessions full of interesting contributions and discussions.

The prevailing note in the convention was the development of preventive medicine in industry

and the promotion of industrial health knowledge among employers and managers. The necessity of proving the value of expenditures for health in industry was deemed of the utmost importance in these times of retrenchment. A note of optimism was prevalent.

The testimony of industrial managers confirmed the optimism. Some of the leaders of business in New England appearing on the program of the dinner given by the Associated Industries of Massachusetts strongly emphasized the permanence of the programs for health in industry. Such approval is nothing less than remarkable in a time when expenditures are being closely pruned. That this new overhead charge which has come into the budget in the last few years should be retained by the leading industries is the best evidence of the importance of health work to modern industry.

New Emphasis on Social Phases of Medicine

ONE of the outstanding features of the Seventy-Second Annual Convention of the American Medical Association, held in Boston in June, was the interest displayed by the officers of the Association, and by visiting physicians, in the social phases of medicine.

Among the prominent exhibits displayed at Mechanics Hall, the headquarters of the Convention, were many of an educational and social character. Such, for instance, was the exhibit of the American Social Hygiene Association, showing panels on social hygiene and preventive medicine, the exhibit of the American Red Cross showing posters and first aid supplies, of the American Library Association demonstrating books used for hospital patients, and of the United States Public Health Service showing educational posters on venereal diseases.

Of great interest were two exhibits, one on community health and tuberculosis, which consisted of a survey at Framingham, Mass. The survey was conducted in a scientific manner and concerned itself both with the medical and social phases of health problems. The exhibit demonstrated that there is no special need of surveying large centers in order to reach certain scientific conclusions; that a survey in a small community often will elicit as much data, if not more, than one conducted in a metropolis. The usefulness of a survey in a small town was also demonstrated recently by the work done in Cleveland. The latter survey has thrown light on many medical and social problems and can be applied advantageously to communal work in large centers.

The second educational exhibit of extraordinary interest was that shown by the Association for the Prevention and Relief of Heart Disease. This Association, which has only been incorporated in the latter part of 1915, has already won its place in the history of medical effort in this country. The Association concerns itself with the prevention of heart disease among children and with the alleviation of the suffering of cardiacs, both among children and adults. The Association has made a survey of children with heart disease in New York. It has opened cardiac clinics, has revised measures for the teaching of children with heart disease; it has opened convalescent homes for cardiac cases; it has made a study of special occupations suitable for this type of patients, and, above all, has done a great deal of educational work, bringing home to the people the importance of the study of heart disease. The literature distributed by this Society is important not only from the standpoint of scientific research, but from the standpoint of preventive medicine, as it is written in easy style so that laymen could understand the importance of the problem.

That the program of the American Medical Association for the coming year includes work along the lines of social medicine is evident by the address of the incoming president of the Association, Dr. Hubert Work. In his address, Dr. Work has called attention to the problem of social medicine in its various phases. Especially interesting are his references to medicine in rural communities, to health centers, to hospitalization, and to group practice, which go to show that with the advance of scientific medicine it has become necessary to pay more attention than has ever been given heretofore to the prevention of disease and to the application of scientific methods to the relief of disease.

Safeguarding the Health of Vacation Seekers

THE rush of people to the forests, mountains, and water fronts for a brief vacation in resorts and camps is a modern phenomenon. Millions leave their homes and ordered life and live for a time in the open with improvised arrangements for food, shelter, and sanitation.

The new life is entered upon with altogether too little preparation on the part of large numbers of people. They do not seem to realize the dangers which lurk in the crowded areas where community control is scarcely known. When the number of vacationists was small the danger was slight; now that they have grown to legions, new efforts for protection must be made.

The organization of summer camps with effective, if crude, sanitary arrangements, and the development of state health departments work in the scattered and remote areas are the answers to the new problems. Summer communities are transient and cannot provide for themselves in a large way. Only by the cooperative effort of groups and by using the resources of the state departments of health can reasonable standards of sanitation be maintained.

Local Health Enterprises Reproduce Themselves

LOCAL enterprise frequently has the effect of provoking national effort, and one of the hopeful signs of the times is the ready transmission of a new idea, however isolated it may have been originally. The Creston, Ia., community organization is an example; nutritional classes for children, another; health center organizations, another. This tendency toward extension of services makes cumulative the constructive influence of such enterprises as the Cincinnati Social Unit, the Framingham Demonstration, and the proposed child hygiene experiment.

Not the least important of the local movements which have become generalized is the thorough-going campaign for the care of cardiacs. Beginning in 1911 as a tentative measure in the form of out-patient evening clinics at Bellevue Hospital, New York City, the success of this work in saving hearts from periods of breakdown and in enabling the patients to continue as wage earners, led to the incorporation of the Association for the Prevention and Relief of Heart Disease. Its activities have extended into preventive medicine, education, and have led to the concentration of medical attention upon conditions apt to promote heart disease, such as major and minor rheumatism, the so-called rheumatic types of chorea, and other diseases likely to be followed by cardiac infections.

A recent issue of the *Lancet* (London) quotes figures from Sir George Newman's report for 1919 which show a steady rise in the number of heart defects in children as well as their occurrence in early adults and middle periods of life, representing, no doubt, cases originating in childhood. The article states that, while much scientific work is being done in England on the clinical side of heart disease, not enough attention is given to the preventive side. It analyzes the high degree of effectiveness of the Brooklyn Cardiological Society and the American Association for the Prevention and Relief of Heart Disease as American standards which should actuate in

England a national campaign against the rheumatic conditions which are the ultimate cause of so many deaths and so much inefficiency.

Social Aspects in Treatment of the Insane

THE social aspects of the treatment of the insane, based on New York experience, constitutes the subject material of one of the Columbia University studies in political science recently completed by Jacob A. Goldberg. The primary aim of the investigation has been to bring before those who are vitally interested in the whole and baffling question of insanity—whether from the viewpoint of the physician, minister, social worker, or layman—facts which will lead to a better understanding of the various phases of the problem.

As a background upon which to picture other aspects of the question, a history of legislation in New York state as affecting the insane was developed. Three succeeding chapters have to do with the process of handling the patient (1) before coming to the psychopathic ward, (2) the patient in the state hospital, and (3) the patient after leaving the state hospital,—thus covering what the state and city are doing for the insane who come under their care.

Inasmuch as the care of the human mind is not altogether a problem for the physician alone, further analysis portrayed the activities of a privately supported social agency specializing in mental hygiene activities. Twenty-five cases handled by the National Committee for Mental Hygiene are presented, which are so selected as to give a fair conception of the problems that confront physicians and social workers in clinics specializing on the side of mental hygiene activities.

In his summation of the general efficacy of service to the insane, Dr. Goldberg finds that the failure of social agencies in given conditions runs parallel with the failure of state hospitals to effect improvement along the same lines; that here, as elsewhere in medical services, low percentages of recovery are due to the circumstance that these cases are not reached soon enough either by mental hygiene clinics or by state hospitals. Institutions would be less crowded and better chance afforded for early recovery if the time before commitment were extended and opportunities extended for observation during that period.

Instead of striving to obtain larger and still larger appropriations for additional state hospital accommodations, the report recommends, as measures to limit the ever increasing need to

maintain in comparative indolence thousands of persons who have or will become mentally ill:

(1) The study and special care, as children, of the groups from which the insane are recruited, giving them the attention which their future welfare demands.

(2) The prevention of the development of unhealthy types of mental adjustment during the adolescent period.

(3) Proceeding on the assumption that in any given community the mental hygiene facilities are not adequate, emphasis should be placed upon the mental health of the population, either through the activities of public institutions and their officers, by private agencies, or both. It should be made plain that, as at present organized, state hospitals are not prepared to meet the mental hygiene needs of a community without the active assistance and financial support of private organizations.

The newer work for mental cases will have to follow these lines in order to achieve a higher degree of success in preventing and curing insanity. "With the public aroused to a deeper interest in all that pertain to the insane, improved methods for treating mental disorders will develop apace."

WHY are you doing the work you are doing, asks a questionnaire recently sent broadcast by the National Board of the Young Women's Christian Association in an effort to determine, aside from independence and pocket money, what part a job plays in the life of the American woman. Do office hours from nine to five o'clock limit the effect of a job upon the life of a young woman? Is the choice of a job made on the promise of good wages, the advice of parents or teacher, or deliberate personal choice above all other occupations? What are the reasons for working—necessity for earning a living, the desire for self-expression, for spending money, or the wish for something to do?

The summation of replies secured from such a questionnaire should afford an index of what is the general attitude of girls toward their work and its importance in their lives.

A RESOLUTION was adopted in the section of public health and preventive medicine of the American Medical Association suggesting that medical societies consider whether or not it is advisable to expel members from the societies who wilfully fail or refuse to report contagious and communicable diseases as required by law. The resolution might better have pointed out that it is the duty of medical societies to expel members who fail or refuse to conform to reasonable laws for the protection of health. Why should there be any timidity in dealing with physicians who deliberately defy the law in matters of such vital concern?

WADE WRIGHT, M.D.

Health Work in Five Industrial Plants

By ALFRED E. SHIPLEY, M.D., D.P.H., DIRECTOR, NEW YORK INDUSTRIAL HEALTH BUREAU, NEW YORK CITY.

IN THESE pioneer days of industrial health work, information is of value which will indicate to those interested in this field, what may be expected as to the types and character of conditions encountered, and means by which such health service may be measured. The practical importance of well kept industrial health records and statistics is their use for administering such a service effectively, and also to act as guide posts for planning future work in an intelligent manner.

While most of the large industries have well established health services, and keep records which are used for their own administrative purposes, so far very little in the way of statistics has been published which will enable comparison of their work with other plants. In this direction, the worthy efforts of the United States Public Health Service are to be commended, and it is to be hoped that an adequate appropriation will be given to them in order that this important phase of industrial health work can be pursued more extensively.

Of the comparatively few small industries which have instituted health

work in their factories, not many are keeping records which will permit comparison of their work with plants of similar size as well as to see where in they differ qualitatively and quantitatively from the service in larger industries.

Smaller Services Organized

The Bureau which the author directs is organizing and administering health work principally in these smaller industries. This service ranges from a complete industrial health program including all the emergency and preventive phases recognized in this field today, down to the emergency service incidental to accidents.

The analyses presented in this article principally concern the clinic service, although some consideration is given to the subject of sickness absence. No summaries of physical examinations of new and old employees, or industrial hygiene features are included.

The extent and character of the work performed in 1920 in the clinics of five of the plants located in New York City and directed by this Bureau are such as to permit com-

parison. In a group of industries so varied in character as these five, the uniformity in many of the phases of clinic service is quite striking and suggestive. The author wonders whether these figures apply to other industries, and will be interested to hear from other factories whose records make these comparisons possible. If such figures hold true, then they may serve to some degree as a basis on which to estimate and forecast industrial health service, as well as to guide in the institution of the very important preventive phases of this work.

A general description of the five plants whose analyses are presented is as follows:

(A) Felt and silk hats and millinery; average number of employees 780, 50 per cent of whom are women.

TABLE II.—AVERAGE NUMBER OF TREATMENTS PER EMPLOYEE.

Plant	Surgical	Medical	All Treatments
A	3.1	2.3	5.4
B	2.9	2.6	5.5
C	4.2	1.3	5.5
D	3.9	1.0	4.9
E	4.2	1.2	5.4

(B) Straw hats, cloth caps, and hats; average number of employees 330, 50 per cent of whom are women.

(C) Cocoa and chocolate; average number of employees 450, 15 per cent of whom are women.

(D) Rubber goods; average number of employees 275, 5 per cent of whom are women.

(E) Paints; average number of employees 225, 20 per cent of whom are women.

In this article the plants are compared only as units. In each factory, records are kept by months which compare the various departments, and

thus permit a definite localization of the health needs. The results of these more detailed analyses may be published at a later date.

The proportions of female employees are noted above, because in the tables which follow, when variations occur in the ratios of surgical and medical cases, they can be ascribed largely to this factor. Greater proportions of medical cases are to be found in plants employing large numbers of women. The author regrets that all of his records for 1920 did not include sex differentiation, but hopes to remedy this defect for the coming year.

The total number of treatments in the clinic rooms at these five factories was 11,089 which were required for 5,738 new cases, both surgical and medical. The details are given in Table I.

The figures appearing in Table I require close study to appreciate the relation of service in one plant to another, but in Tables II and III some of these facts are presented in ratio form. Table II shows the average number of treatments per employee, which is obtained by dividing all treatments by the yearly average number of employees.

The remarkable feature about Table II is the uniformity in the average number of all treatments. This is true despite the variation in the two factors which make up this total, i. e., the surgical and medical; and this variation applies only to Plants A and B as compared with Plants C, D, and E. Each of the factories A and B employs 50 per cent of females and this is the principal reason for the larger proportion of medical treatments.

In each of the five plants, the average number of clinic treatments per month may be estimated as approximately one for every two employees. The author has discussed this feature with other factories in New York City and reference to their records has disclosed the same averages.

In Table III the figures shown in Table I are reduced to percentages. For the surgical cases there is such a remarkable uniformity in the proportion of re-visits as compared with the first treatment that the average for the five plants is justified, and we can state that for every new surgical case two re-visits are necessary. The ratios for the medical cases are fairly constant also. The relatively small proportion of re-visits here is due to the prompt relief afforded, or, in the more serious cases to their immediate reference to the family physician for further follow-up. In the other three columns noted in Table III, Plants A and B fall into one group of consistent averages and Plants C, D, and E into another group. The differences between the two groups are due to the relatively larger proportion of females

employed in A and B, as was mentioned previously.

When a further analysis is made of the new surgical and medical cases as presented in Table IV, the same uniformity is shown to exist in the character of clinic cases seen in these five industries. This is particularly true of the surgical cases. If these figures serve as an index of industrial surgical work, then 50 per cent may be expected to be finger cases and about 70 to 75 per cent, conditions affecting the entire upper extremity.

In the medical group where variations occur they can be explained for the most part by local conditions, which being recognized permit forecasts and conclusions upon which to base preventive measures in the administration of the respective plants.

The teeth treatments are merely those incidental to caries, such as toothache, and do not include any prophylactic measures advised at the time of the physical examination of new or old employees.

In general, the number of cases in the five plants for any one of the factors noted in Table IV is in proportion to the number of employees in each plant, this rate being only modified by the relative number of females employed, for reasons noted previously.

For current use in these five factories, each one of the factors appearing in Table IV is kept showing the various surgical and medical affections treated. This entire record is too detailed to present here, but in order to show how these different ailments occur, one surgical group is shown in Table V and one medical group in Table VI. In addition to the larger proportion of males in Plants C, D, and E, the use of more and heavier machinery accounts for the relatively large number of surgical conditions in these three factories.

These tables also show the need for uniform diagnoses. For instance, in Table V the abrasions in Plant B are too few; probably they have been entered on the records as lacerations. Again, in Table VI the influenza and grippé cases at Plant B are too few, and undoubtedly have been recorded as other respiratory affections.

In order to see whether the clinic service reflected general community health conditions, a summary of the respiratory diseases by months was made and is shown in Table VII. Beginning with the high point in January, there is a gradual decline until July is reached and then a steady increase until the end of the year. This would be considered generally as a characteristic respiratory disease curve.

When this table was made up, several discrepancies requiring investigation were apparent to the author, the most prominent being the great disproportion of cases in February be-

tween Plants A and B. A ratio of two or three to one should obtain in these factories. Upon looking up the records, it was found that the clinic physician at Plant B had been very irregular and neglectful in his attendance that month and this was reflected in a decreased clinic service. He was replaced by another physician in March and at once the normal clinic service was resumed. This is cited to show how one can gauge within reasonable limits, the health service for a given plant, and investigate when it rises or falls beyond these limits.

In Table VIII an analysis is given of the accidents occurring within the

jurisdiction of these five factories.

The large number of infections in Plants A and B was due in great measure to neglected needle pricks, which occurred despite an energetic campaign to secure proper treatment of these puncture wounds. It was difficult to make these needle workers realize the danger from such apparently insignificant wounds. On the other hand, the few infections in proportion to cuts and lacerated wounds in Plants C, D, and E was due to the free bleeding and necessity for prompt treatment incidental to the nature of the injuries.

In reviewing the causes of these accidents it is found that very few are due to lack of mechanical guards but that the vast majority are the result of carelessness, inattention, poor physical condition of the worker, or some other personal factor.

Most of these accidents were of the first aid type, that is to say, the employee returned to work after the wound was treated in the clinic room. If the patient did not return to work it was reported as a Compensation case. By reference to the table it will be seen that such cases were comparatively few, and most of these came back to their occupation in a few days.

In Plants A and B records of sickness absence are kept by which the relation of this factor to other causes of absence can be determined. Another record gives the illness causing the absence with the total number of days away from work for each case. The records are not complete enough, neither do they extend over a sufficient period of time to draw very reliable conclusions therefrom as yet, but a few of the summaries are presented as matters of general information.

In Table IX the tabulations for only six of the twelve months are given as the other months are incomplete or unreliable due to the seasonal character of the industry, and also to rapid variations in the number of employees, because of the general unsettled industrial conditions toward the end of the year.

It may be noted that on the average, about 50 per cent of the absence was due to sickness. This is more than the 33 per cent reported for an eastern manufacturing company, statistics of which were published in the United States Public Health Report of September 10, 1920. But absence under two days' duration was not considered as due to sickness in that report, whereas all sickness absence is

included in the figures of Table IX. A very large proportion of absence due to sickness is of the one and two day type as will be seen by referring to Table X. When these differences are taken into consideration the figures in these two reports on absenteeism are very similar.

Table IX also shows less sickness absence in September and October than obtained in the earlier months. A smaller amount of actual illness accounts for some of this reduction, but another reason was the decreasing demand for workers; that is to say, employes are not inclined to stay home for trivial ailments when they know their places can be filled readily.

In order to determine the duration of absence due to illness, records were started in July, 1920, in Plants A and B, showing the length of time each individual was away, and the character of the ailments causing the absence. The latter feature has not been compiled yet, but in Table X a summary of the duration of absence is given. At Plant B, work is very slack during the summer so the tabulations there cover four months only, but these will permit ratio comparisons. The number of absentee days covers the working period only and does not include Sundays.

In Plant B a very interesting analysis was made last spring, immediately after the April figures were

compiled. It was found that whereas the general factory absence was 6 per cent, the Straw Trimming Section was 12 per cent. This section employs a female help of varying ages, the large proportion, however, being young

women. The Works Manager thought this excessive absence was due to the girls and younger women, and so it was decided to divide the absentees into age groups, with the surprising contrary result shown in Table XI. More than one-half of this absence was due to illness, the large part of which was in the women above 40 years of age, due to more serious ailments, and slower convalescence.

In conclusion, the author wishes to emphasize the practical importance of facts such as presented in this report. They are not matters merely of academic research, but to those trained to interpret such readings they provide the means to administer industrial health service intelligently

and effectively. Furthermore, the keen, practical factory manager appreciates facts which show him the health status of the human power under his direction, and enables him to compare conditions in his own plant with those in other industries.

Association Officers Elected

THE recent meeting of the American Association of Industrial Physicians and Surgeons in Boston was attended by a large and representative group of industrial physicians and surgeons, all of whom are actively identified with the Association and are severally responsible for much of the outstanding achievement in industrial medical service during recent years. The general participation in the discussions and the wide range of problems which occupied the attention of the assembly bespeak the influence of medicine in industry.

Officers for 1921-1922 were elected as follows: Dr. C. E. Ford, General Chemical Company, New York City, president; Dr. C. F. N. Schram, Fairbanks, Morse & Co., Beloit, Wis., vice-president; Dr. L. A. Shoudy, Carnegie Steel Company, Bethlehem, Pa., second vice-president; Dr. William Alfred Sawyer, Eastman Kodak Company, Rochester, N. Y., secretary and treasurer.

Directors as follows were elected to serve from 1921 to 1923: Dr. C. A. Lauffer, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.; Dr. G. H. McKinstry, Spang, Chalfant & Co., Inc., Pittsburgh; Dr. L. Noland, Tennessee Coal, Iron & Railroad Company, Birmingham Ala.; Dr. C. H. Watson, American Telephone & Telegraph Company, New York City; Dr. W. B. Fisk, International Harvester Company, Chicago; and Dr. Ralph W. Elliott, National Lamp Works, Cleveland, O.

The directors held over from the previous years are: Dr. Philip King Brown, San Francisco, Cal.; Dr. C. M. Harpster, Toledo Railway & Light Company, Toledo, O.; Dr. C. W. Hopkins, chief surgeon, Chicago & Northwestern Railway, Chicago; Dr. Harry E. Mock, Rush Medical College, Chicago; Dr. R. H. Hourigan, The Larkin Company, Buffalo, N. Y.; and Dr. J. A. Watkins, Lunkenheimer Company, Cincinnati, O.

Industrial Sanitation Affects Public Health

By S. DANA HUBBARD, M.D., SUPERINTENDENT, DIVISION INDUSTRIAL HYGIENE, NEW YORK CITY DEPARTMENT OF HEALTH, NEW YORK CITY

IT MAY be stated that the health of a group is in a very definite degree dependent upon current sanitary practices, but, in industry, problems of sanitation become highly complex and relate quite definitely to provisions of equipment. Perhaps it might be safe to assert that in industrial establishments, no item so essential to comfort and health is so seriously neglected by employers and so abused by employees as the equipment of toilets, urinals, etc.

Toilets are regulated in New York City by law. This considers kind, number, location, ventilation, etc. The Industrial Code and the Sanitary Code specifically deal in minutiae with toilets, demanding separate toilets for each sex in every factory. Unfortunately there has been omitted responsibility for providing toilet paper and this oversight at times results in the use of heavy paper or newspaper which blocks the drains.

Proper placing of toilets is an important matter; whenever practical, toilets should be provided on each floor giving careful consideration as to the distance employees must travel from their place of work.

Much expense of upkeep and inconvenience would be eliminated if engineers and architects would select for industrial establishments a standard toilet equipment and industry should demand a standard of care for these places. For the sake of cleanliness, toilets should be constantly supervised, regularly cleaned, and occasionally disinfected and if damaged or out of order immediately repaired.

Safety in Standardization

The washing of the toilet with a hot solution of sal soda—three gallons of hot water to one pound sal soda, or a strong acid solution, muriatic acid one-quarter strength, materially aids in removing stains, and destroying the strong urinous odors.

The urinal is a subject on which the sanitarian could spend considerable time with much comfort to the public health. Urinals quickly foul and but few seem to know how to clean and keep clean these affairs. As an interesting experiment, collect some urine in a small metal or glass dish and set it aside. In less than a day it is cloudy, turbid and odorous—the stench being exceedingly unpleasant.

This demonstrates the necessity for care of the urinal. Now clean the metal dish by emptying the contents and flushing with cold water, as is ordinarily done in cleaning urinals and it will be found that cold water will not remove the deposit nor the odor. Hence scouring is necessary properly to cleanse and keep them sanitary. A visit to an up-to-date hotel, railway station or large office establishment where care is given to these places, will reveal that the lavatories are clean, orderly and free from unpleasant odor. Further there will not be the strong aroma of cresol to disguise the urinous stench. One of these bad smells is as unpleasant as the other and neither is necessary. How is this cleaning done? It is not accomplished simply by leaving things alone and trusting to the stereotyped sign—"Please flush after using"—but these places are in charge of an attendant who is held responsible for their cleanliness.

In some establishments proprietors expect their workmen to leave the premises and use toilets provided either by public places or those accessible to the public. The law specifically requires that toilets be provided. In the sparsely settled districts, toilet accommodations are located outside of the building and at some distance from the place of work. This causes a loss of time and in the cold season endangers the health of the employee. Toilets should be located within a factory, preferably on an outside exposure in order to secure light and ventilation. It is a very safe rule to provide toilet accommodations on each floor. In some of the tall office buildings the toilets for men are on one floor and those for the women are on a different floor. All toilets should be plainly marked and the doors should be provided with bolts in order to secure privacy. It is a good feature to have distinguishing lights at night indicate the location of the toilet. Some establishments have markers in the hallways showing the location of the toilets.

The toilet should be in charge of a committee of workers—the shop sanitary committee—whose duty it should be regularly to inspect these places, and report on special cards furnished, the conditions found on each inspection. If this were done,

many of the objectionable conditions which are frequently complained about and which often are incident to improper practice by the workmen of the shop, could be quickly detected and in many instances prevented. This committee should be changed sufficiently often to give each employee of the shop an opportunity to serve and in this way become familiar with house sanitation and the necessity for such. Shortage of toilet paper and the stopping up of basins would be detected promptly and opportunity given to have such corrected before it puts the apparatus out of order. In one establishment alone this cut the expense of toilet operation 50 per cent in less than one year.

Standards of Equipment

Architects and engineers should consult the sanitary authorities in factory construction about toilet accommodations and these authorities should endeavor to devise a good practical sanitary toilet equipment of a standard variety. Mr. Fitch, a safety engineer of note, suggests the following standard toilet equipment:

(1) Location on outside wall, for light and ventilation.

(2) Solid porcelain closets with open front type of seat (horseshoe shaped), the seat automatically flushing the tank and after use raises so as not to be wetted in case this basin is used as a urinal by men.

(3) Each closet to be enclosed in metal and furnished with automatic closing doors. The door to have an inside bolt to insure privacy.

(4) Each toilet to be at least 90 cubic feet in area.

(5) Floor to be concrete, pitched to a floor drain.

(6) Hose bibb water supply for flushing and washing. Every toilet to be washed with a disinfectant every day.

(7) One toilet for every five or multiple of five workers.

(8) Full length porcelain urinals equipped with water supply for constant flushing and separated by a full length screen to insure privacy. The urinal to be set on a slate slab with concrete border, tapered so as to form drain to waste.

This standard is sanitary, practical and efficient.

Common drinking cups are dangerous and are in violation of the law.

Individual cups should never be loaned as this practice may spread disease.

Clean, cool, wholesome and an ade-

quate supply of drinking water is necessary and essential to the health of workmen. The law requires this service because it is necessary for health.

Drinking water is necessary not only within the shops but such should be accessible to yard workers and to messengers. For these reasons there should be frequent opportunities for people to obtain a drink on our highways. There is a strange situation regarding our public drinking places. In the parks there is an abundant number of drinking fountains of the most approved type, but on our streets and avenues the reverse is the situation. Why?

In the shop the drinking water and its source should always be carefully supervised. Many instances of tank collection on the roof have shown the necessity for this supervision. Animals seeking water get drowned in these unprotected tanks and a floating carcass is not unusual to be observed by our inspectors. Sediment, especially when tanks are in the vicinity of dust producing places, collects quickly in the bottom and on the surface and either discolors or flavors the water with a disagreeable taste. The roof of a water tank is rarely ever painted or metal protected and this cover when made, being exposed to the elements, rots and the decayed debris gives to the water a distinct "woody" taste and smell. The roof tank is also a mosquito breeder when it is uncovered.

The location of the water tank is deserving of consideration as quite a number of tanks have been found located in improper places. This division is now trying to have some factories remove the water tank from water closet compartments. No doubt here, with improper ventilation the drinking water may become foul or contaminated, especially as in one instance a woman was found washing her hands in the tank after performing the functions at the toilet. It seems unbelievable that a drinking water tank would be purposely placed in such locations but where room is scarce and rents high the propriety of such is scarcely questioned by those indifferent to the health of the worker of the community.

The common drinking cup is worthy of closer consideration. Science has abundantly proved the common drinking cup to be a menace to health, yet it is observed quite often in our shops and while there is a statute prohibiting, its presence is daily observed in many establishments. It is inimical to health and should be abolished. Managements destroy the common glasses, tin cups, and old cans or jars furnished by workmen; but, unless salutary discipline and education impress the men and women, this violation will continue. The legal notice should be posted at each drinking place and all workmen should conscientiously live up to this requirement as it is necessary for health. Some of the most loathsome of the in-

fections—syphilis—have been spread through the use of the common drinking cup. *Away with it.*

The problem of the individual cup has not been solved. Either the workers should be made to provide their own cups or else individual service should be furnished by the establishment. This service has been solved in our trains, ferries and hotels, and industry would be wise to follow suit. Many workmen are not informed of the dangers of the common cup and so our industrial inspectors are kept busy explaining the reason for this necessary regulation.

A drinking fountain with an angle stream will do away with the cup problem entirely. There are many sanitary models on the market, but a good practical one may be made from the ordinary spring faucet, inverted and the lips prevented from touching by a wire guard mounted on a tripod. Several of these have been installed in our public schools and they solve the problem admirably.

Ice should never be placed in the drinking water as it is likely to be surface soiled or else have in its interior germs (typhoid) which may cause illness. Many germs are resistant to cold and therefore the law forbids ice being placed in the water.

The space about the drinking fountain is often very insanitary—wet, slippery, and dangerous. It is rather common practice to throw on the floor the water not used. This is pernicious as the wet floor in time rots, the moisture is dangerous to walk upon and the wet stained floor is unsightly. Waste receptacles should be provided and workmen should be made to use these, in the interest not only of cleanliness but of safety and health.

Lockers and Wash Rooms

Until quite recently little or no consideration has been given to the comforts of workmen and working women in this respect. Damage to clothing and loss of garments by petty pilfering have been the source of much dissatisfaction among workers and complaints about inadequate locker space are constantly reaching us, complaints which are in many instances justifiable. Workmen should have a place to hang their clothing and hats and leave their lunch boxes where such articles will be kept clean and secure. Lockers should be fire proof, vermin proof, and placed in a location so as not to absorb odors. Locker rooms should be readily accessible. Not infrequently industrial establishments expect workers to hang

A neat, modern, up-to-date first aid room in charge of a first aid attendant assigned by one company. Every care is given to the injured or sick in a most efficient manner.

In this metal factory the worker repairs and replates electric chandeliers in a dark room with no windows, dangerous work benches, unventilated cauldron, and with aisles obstructed with litter and trash. The labor turnover in this shop was 60 per cent.

their belongings on a peg or nail near the work bench or place them in some out of the way location only to find later that the lunch has been stolen, pockets picked, or the garments taken. These little annoyances materially disturb even the most complaisant. In establishments requiring a complete change of clothing lockers are a necessity in the interests of decency and health. Conditions which make it necessary for women to change garments in places exposed to the view of the other sex are demoralizing and manifestly improper though it has been observed by our staff quite often. The careful storage of the clothing while at the shop is essential to the comfort of the workman.

Lockers should be constructed of metal, connected in units and be of the hygienic variety—on legs some distance from the floor. The door should have a key which should be in the possession of the user of the locker. The locker room should be handy so that in case of fire or panic the worker may remove property without undue loss of time. Lockers should be ventilated in order to be sanitary. They should be of sufficient size as to permit the garments to be hung comfortably without wrinkling or mussing. The rolling of garments and sticking them into pigeon holes makes the worker dissatisfied and, further, if the worker is not encouraged to be neat in dress he will not be tidy in his work. Slovenliness is one of our besetting sins. It requires education to be orderly.

Lockers should be systematically inspected and should be cleaned at least once a week. A good plan adopted by many establishments is to have the

lockers empty and on Saturdays or once a week have them scoured. If the locker service is large it warrants an individual keeper who should have entire charge and be held responsible for the cleanliness and condition of the lockers. Lockers should be free to all workmen. Where a locker fee is charged to the worker it has bred discontent has afforded the worker an excuse for disliking his job. The individual metal locker is a necessity and sooner rather than later the sanitary locker will be made to replace the peg or hook.

Washing Facilities

Have your workmen opportunity for cleaning up? If not, why?

Surely no one should go from the workbench and eat lunch without cleaning the hands. Certain indeed no one should leave a toilet and not cleanse the hands.

The statutes under certain conditions require washing facilities—bakeries, lead workers, etc.—and in some instances the laws require the provision of hot water and soap.

In certain occupations, such as foundries, shower baths are required by statute.

Why should employers have to be forced by law to provide that which even a casual observer could quickly determine to be not only essential for the comfort of the workmen but necessary in the interest of efficiency.

It has been only recently that public attention has been centered on these conditions and, while the period is short, yet the favorable reaction has been marked, as today the washing facilities are adequate in many of our industries.

It might not be too much to require of every industrial establishment where there are a number of workmen employed to have adequate washing facilities provided. In many instances these facilities should include not only places for hand washing with hot and cold water or both, but in trades where the workman is distressingly soiled, as in coal handling, firing, oiling, etc., shower or tub baths should be provided. This is in the interest of public comfort. For, who likes to meet in public conveyances these soiled workmen who through no fault of their own, are by reason of their soiled garments a public nuisance. This is most unfortunate and must be embarrassing to the individual; but under circumstances which provide no lockers, no washing facilities, if the workman resides some distance from his work, he is forced to travel with untidy person and habili-

ments. It demeans his self-respect and is provocative of argument while in transit. A condition of this kind is unnecessary. With wages as good as they are there is no need for the individual not having two suits, provided he has a place to wash up and change his garments. We feel keenly for these individuals. Many plants have no washing facilities and oftentimes workers have to eat their lunches without being able to wash their hands, or after attending to the functions of nature cannot do so owing to the failure to provide these facilities. Should a typhoid convalescent return to work under such circumstances and be a carrier of organisms, such a procedure would be exceedingly harmful to the community. It is pleasing to be able to state that as soon as these facts are brought to the attention of industrial agencies much has been done to stop these very insanitary conditions, but much is still to be done in this direction.

An available wash basin, preferably supplied with hot and cold running water, soap and individual towels is demanded in the interest not only of bodily comfort but are actual health necessities.

Shower or Pool Bathing

Nothing so rehabilitates self-respect as ablution.

We will not consider the subject of baths in general as volumes may be written and any one interested may learn some valuable information regarding this subject by consulting the Encyclopedia Britannica under the caption Baths. What we are concerned with is the necessity from a sanitary health point of view of the need for bathing in industrial work.

In dyeing establishments, dusty trades, or industries in which fumes constitute a problem, there should be provided shower bathing facilities. These are very helpful in the heated season, but in certain industries are essential at all periods to body comfort and health.

In large foundries and in establishments where there is considerable dirt—flour mills, foundries, plaster mills, coal passing, printing establishments, paint works, garages, and chemical plants—shower bath facilities are necessary, and in some of those mentioned are required by law. In fact it might be stated safely that every industrial plant ought to have a few shower baths connected with the locker room, the number of showers required varying according to the nature of the occupation and the number of workmen requiring such serv-

ice. If the work is dirty, and grimy, and particularly if poisons are used, workmen should shower before leaving for home, especially when they change all of their clothing upon entering or leaving the mill.

Under no circumstances should night workmen or others be permitted to use roof tanks for pool bathing. This has been detected and it not only fouls the tank but contaminates the water which may be used for drinking purposes. To prevent this, roof tank doors should be padlocked.

Lunch Room Necessary

Where workmen are some distance from their homes when employed or where local public establishments do not afford service or the employee cannot stand this additional expense, there should be provided, places,—especially in the cold season and on wet days—where men and women may gather and eat their lunches comfortably. In some places separate quarters are provided for the sexes, though this is not always necessary. Many establishments provide lunch rooms and some even furnish the lunches. Some of our large banking establishments are finding that it is service well worth while, and in many places where night work is performed the midnight meal or lunch is prepared and served away from the work bench.

In the warm season outdoor facilities in plants having yard room should be set apart for lunch service. In one of our large mechanical plants a lunch yard has been established where music, singing and many forms of recreational activities are undertaken during the lunch period. Having witnessed the operation of this service on many occasions we can testify as to its helpfulness. In co-operation with social, religious, and public health activities there has been some splendid work of a social and educational character performed in this yard lunch service. Near one of the large barns of one of our street railways the recreational yard is of quite pretentious proportions. Workmen should be encouraged not to eat their lunch in the shop. In certain poisonous trades strict regulation forbids this practice. Health demands the change and the workman as soon as he learns of the effect of this practice on his disposition and his health soon takes up the innovation and continues it.

The division of industrial hygiene for some time has advocated suitable lunches and in order to aid the worker, prepared a free booklet,

It took two lawsuits to bring the owners of this insanitary metal workshop to improve the unhygienic conditions. The exhaust system was not operating and defective, the work was done under crowded conditions, and limited light made it dangerous.

"Keep Well No. 17," on how to prepare and serve economical, well balanced, and suitable lunches for the workingman. These may be had for the asking.

A suitable carrier became necessary when prices soared so high that eating in food establishments was practically prohibited and the workman untrained as he was did not eat that which his system demanded. This carrier has a vacuum bottle for carrying hot or cold liquids, a metal container for keeping food properly, and has ample carrying capacity for a very hearty meal. The container is fiber and is neat and indestructible. It retails at about four dollars. Since starting this agitation it is not unusual to observe many hundreds of our workers, both men and women, taking their lunch to the shop. Health demands food and to provide what is suitable and economical is indeed a problem.

The sanitation of lunch rooms is frequently neglected. After use the place is littered with all forms of trash, indicative of carelessness. Here we have endeavored to get the worker's attention and where these talks have been given the lunch room is neat and tidy and the sanitary committee quickly disciplines offenders by mock trials. This affords sport for those present and is a salutary example, preventing repetition of these offenses against decency. The lunch room should be kept "spic and span." The success of the lunch room is dependent upon intelligent co-oper-

ative effort. After all, we are only human and we have pride not only in our dress but our plant and tidiness and good sanitation are essential to efficiency and success. Cleanliness is next to Godliness, and it has been frequently observed that the better dressed and the cleaner the plant the greater aid is sanitation to happiness and splendid service. Men and women too are going to be attracted to the plant which has good and clean work places. The plant which has a high regard for sanitation is going to have a reduced labor turnover, a pleased staff, and will get an adequate return for the expense incurred.

Mirrors Added

We have these in our homes—yes, both men and women. Why should not mirrors adorn our shop walls? This may appear to be fastidious, but to go even into a blacksmith shop and find a fragment of a mirror reposing safely in a corner near the wash basin indicates that there is a need for a reflector near every washing basin. But few individuals can part their hair without using a mirror and every possible inducement to encourage personal tidiness is a distinct aid to improved personal health and general sanitation. By all means let the men and the women have a good mirror near the wash basin in every shop.

We overhaul our machine. We look after it constantly. Why not give our bodies the same vigilant care and consideration?

If disease broke out like a fire, we could all run when the excitement started; but, unfortunately, those diseases most destructive of human life and human efficiency begin insidiously, stealing upon us like a cat upon a mouse. They are well implanted before recognized and then our medical adviser informs us it is "too late."

A medical examination is an affair of the doctor and the individual and should be as confidential as a consultation between a private paid physician and his patient. Abuse of this privilege has caused many workers to avoid the medical man and this is most unfortunate.

The division of industrial hygiene will make a confidential physical examination in private and personally advise the examined, free of charge. Many hundreds of these have been made. We also say if you do not want us to do this, see your private doctor occasionally and have him overhaul your body; or at least see the plant physician, who is ready and willing to help you in the interest of industrial efficiency. Heretofore it

has been the practice of industry to let the workman gravitate to his proper sphere of usefulness because labor was plentiful and material cheap. The war and its many changes has reversed this condition and today trained labor is scarce and material costly. Similarly, changes in the staff have been found to be uneconomical both to capital and labor.

The recent experience in the selection of men in the draft, astonished many who were unaware of the poor physical condition of our youth, but it has been appreciated for many years by experienced sanitarians that from 50 to 75 per cent of our school children suffer from some remediable physical defect and to find only 33 per cent physically unfit, in a higher group, was, on the whole, encouraging.

Many of the physical defects that impair physical effort are trivial in character but neglected soon develop into serious conditions. "For want of a nail a horse was lost." "A loose screw often is the cause of a broken door."

resorts and hotels, show that 45 per cent incident to human carelessness we are appalled. Fairly reliable statistics inform us that only 12 per cent of industrial accident cases, however, are directly attributable to machinery. The obvious is evident.

In considering the promotion of health and longevity of life heretofore officials have been concerned chiefly with preventive measures controlling disease as the chief factor in precocious shortening of life.

The importance of industrial hygiene has been only partly appreciated and many of the schemes to put this into effect have been rather imperfectly carried into execution. In many instances personally known by us it has been only half-heartedly done. This condition must be changed. To save life and reduce unnecessary sickness and accident expense this work must be carefully planned and scientifically executed, expecting that through sanitary shops our jobs will not be a menace to our workers' health and a debit against public health.

Mobile Laboratory in Michigan

MICHIGAN'S "laboratory on wheels," instituted last summer for the purpose of inspecting sanitary conditions at re-

approximate starting point for the motorized laboratory, which will be manned by two bacteriologists and a sanitary engineer and will work

cent of the water supplies were found unsafe, that half of the resorts had no adequate method of garbage disposal, and that 47 per cent of the milk samples analyzed revealed a higher bacteriological count than is allowable for "reasonably clean" milk.

"People who go to summer resorts," says Dr. Olin, "are in need of an abundant supply of good, wholesome food—especially milk. Many are in such a physical state as to suffer serious consequences from contaminated water or food. No more effective work, therefore, can be done in protecting the public health and the reputation of the resorts, than careful supervision of water, milk, and food supplies."

"If Michigan wishes to maintain the name it has earned—'the nation's summer playground'—its resorts from now on must stress sanitation. People in cities are learning the value of sanitation, and in choosing a place to spend their vacations will come to demand the same protections they are afforded in everyday life. Vacation typhoid will be a thing of the past when effective sanitation is carried to every part of the state, rural as well as urban, and one of the most interesting developments in sanitation is the mobile service."

Michigan's laboratory on wheels can be rushed to the points where disease foci exist, and thus protects the health of the vacationist. Incidentally it conserves the summer resort industry, an important economic feature.

sorts throughout the state, will be in the field this season from the time the first vacation enthusiast arrives until the last one leaves, announces Dr. R. M. Olin, state commissioner of health. Ludington, Mason County, will be the

Physical Standards for Child Laborers^{*}

Surely Our Society Does Not Need to Live on the Earnings of Its Young

By S. JOSEPHINE BAKER, M.D., D.P.H., DIRECTOR OF THE BUREAU OF CHILD HYGIENE, DEPARTMENT OF HEALTH,
NEW YORK CITY

ADEQUATE protection for the child after it enters industry has demanded that effort be largely devoted to prevention as well as to the correction of wrong conditions after they have occurred.

The National Child Labor Committee has called attention to an existing condition that is worthy of the deep consideration of all who are interested in the welfare of the child and its effect upon future generations. In *The American Child* for November, 1920, this Committee states that:

(1) There are at least five and a half million illiterates in the United States.

(2) Nearly one-fifth of all American children between the ages of ten and fifteen are out of school, earning their own living.

(3) Illinois, Iowa, Kansas, Maryland, Minnesota, New York, Pennsylvania, Texas and Wisconsin all report a startling increase in the number of children leaving school to go to work in the year 1920.

Investigations would also seem to show that only 4 per cent of the children in the elementary schools enter high school, and only about 1 per cent of all children finally enter college.

One Child in Five Works

In the United States there are approximately eleven million children between the ages of ten and fifteen years. According to the statements just given, therefore, we have approximately 2,200,000 children at the vitally potential ages of from ten to fifteen years, engaged in some form of industrial occupation.

It would seem that the time has gone by for any argument as to the need of protecting our children against exploitation. Whatever may be our conception of a world in which social justice will be the rule for all, we must consider one fact as basic: social justice for children is essential. This is still denied because, in my opinion, people have not yet been sufficiently aroused both to the extent to which it is denied and to the importance of measures which will mean

full protection for every phase of child life and progress.

During the latter years of the war, children were apparently needed in industry to a greater extent than ever before. It is probable that many doubtful arguments were put forward as to the extent of the need of children in industrial occupations even during that period. With the ending of the war, however, such an emergency may be considered to have ceased. According to the authority quoted above, however, the tendency for children to leave school and go to work is on the increase instead of on the decline. The Committee states: "More children have left school to go to work in 1920 in many industrial centers than in 1919. Fourteen states report an increase in child labor during the first six or eight months of 1920 as compared with the same period last week. In New York City 5,283 more children applied for work permits in the first six months of 1920 than in the same period last year, but in the last three months there has been a decrease in applications, so that the total increase is only 2,353. In Baltimore County, Maryland, there were 4,064 more applications for work permits up to October 31, 1920, than in 1919, while during the summer the Chicago authorities reported an increase of 13,000 in that city, and in Minnesota there has been an increase of 193 per cent since 1915." The further statement is made: "The place for every American child up to sixteen, at least, is in school, and we have proved that by mothers' pensions, child labor scholarships, and other devices for public aid, even poor children may be kept in school. The child who goes to work at fourteen has an earning capacity at twenty-five just half as great as the child who stays in school until he is eighteen; and the child who goes to work at fourteen is twice as liable to sickness and disability as the child who stays in school. In fact, the loss to the nation in health, efficiency and happiness, created by premature employment, is incalculable. As Mr. Hoover puts it, child labor is 'poisoning the springs of the

nation at their source.'" The present time offers unequalled opportunities for the protection of the child. The war taught us the value of human life and the United States is now following the example of Europe in devising and putting into effect many forms of child welfare work. Never before has so much attention been given to the essential needs of childhood.

Child's Needs Foremost

At the present time, industrial conditions, particularly those pertaining to employment are reverting to their pre-war status. Whatever the needs of industry for children may have been in war time, we may be sure the conditions of adult employment at present, and increasingly in the future, will make the employment of children less and less essential. It will probably be true, for the next few years at least, that where children are employed to any extent it will not be because of the need of them in industry but because they can be employed at a wage far below that for the adult worker. Such a course can only result in harmful exploitation of the child, without any benefit to a sound industrial policy. There is another point of view from which we must consider the relation of the child to industry, and that is that even when industry shows an apparent, even if dubious, need of child labor, only the minor premise of the argument is stated. The main point to be kept in mind is not *industry* and the child, but the *child* and industry.

We are not arguing with regard to the present alone when we consider our attitude towards child labor. There is a later aspect to the matter, as has already been shown; that is, the productive capacity of children who have been well prepared is greater than for those who have spent less time in school, but the immediate economic question relative to the use of child labor should not be considered as worthy of discussion when compared with the need of a sound policy for the protection of children.

It seems futile to discuss the results

^{*}Presented before the Eleventh Conference of Industrial Physicians and Surgeons, held under the direction of the Department of Labor and Industry of the Commonwealth of Pennsylvania, Philadelphia, Pa., December 17, 1920.

of gainful occupation upon children when the fact is so clear that children should not be employed at all. The action of the Supreme Court in declaring unconstitutional the Child Labor Law recently passed by the United States Congress is, of course, a sound legal action, but the purpose of the law marks a milestone in the right direction. If the United States government by Federal enactment cannot settle the question of child labor, the individual states have it well within their power to do so, and in one way at least the United States government has now taken steps to suggest standards for the normal development and physical fitness of working children.

Early this year the Children's Bureau of the United States Department of Labor called together a committee of specialists in child welfare to formulate a set of standards which would serve as a basis for those to be adopted by the various states, as the minimum health requirements for all children who expect to enter industry. It is true that such standards have no direct administrative or legal authority, as they are promulgated by the Federal government, but their moral force is strong and they point the way for enlightened state action. While the Committee as a whole has not reported, and while it is too early to give definite information about the form of their report, I think it is possible at this time to mention some of the physical standards which are considered the minimum that should apply to children entering industry. These conclusions should in no sense be considered as reflecting the views of or as coming from the committee in question. The majority of the standards outlined are those of New York City and have been proved to be entirely feasible and of the greatest importance to the welfare of the child.

Age Limit in Law

There is practically no state in the Union that requires a child to be over fifteen years of age when it first enters industry. The ages at which a child may go to work range from ten to fifteen years.

We may dismiss without comment the deplorable condition of affairs that would allow any child between the ages of ten and fourteen years to be employed in a gainful occupation. Such laws are barbarous, and a decent and enlightened public sentiment should demand their repeal. It is also questionable whether any child under sixteen years of age should be allowed

to enter the industrial field. No one can reasonably expect that children under sixteen years of age can be entirely kept away from home occupations or the minor forms of helpfulness which every boy and girl enjoys. There are many kinds of employment which cannot have any serious effect upon the health of children, when they are under family supervision, when only a few hours a day are devoted to the employment and when the work is liberally interspersed with play. The difficulty, however, is that there are no laws which would limit occupation at these ages in this manner.

When a child is once allowed to go to work, there is very little control over the type of industry which it enters. It may be an industry requiring an amount of strength and endurance far beyond the physical ability of the child to supply, or it may be one which, from its very nature, is injurious to the health of the child.

Any form of industrial employment may be harmful to children during adolescence. It may not be essential to afford the same protection to boys during this critical period of life as it is to girls, but certainly the boy between fourteen and sixteen years of age should not be subjected to any unusual strain, and the girl between fourteen and sixteen years of age should not be allowed to have any physical strain at all. When one remembers that in the United States 35 per cent of all infant deaths occur during the first month of life, and that this large proportion—one-third of all baby deaths—is due to conditions affecting the health of the mother before the baby is born, it will be realized that the effect of industry upon girls during the period of puberty has not yet been fully measured. There can be no doubt whatever that many type of employment to which the adolescent girl is subjected can have such serious and far-reaching effects that they may be shown not only in chronic invalidism to the girl in question but may seriously interfere with the possibility of motherhood in her case and may even be detrimental to the health of the next generation. There can be nothing clearer, to my mind, than that it is the duty of the state to protect the health of children and women. Therefore, it would be desirable if a minimum standard age of sixteen years could be established in all states for the entrance of children into industry.

From a physiological point of view, these children should be kept under observation until they are eighteen

years of age, and repeated physical examinations should be made of them at stated intervals during the two years, in order to determine the effect industry has had on their physical well-being. If any deleterious effect can be shown, provision should be made in the law that such child be barred from industry for a period of time necessary to regain health.

Character of Occupation

The type of work the child performs may have a most important bearing upon its health. For that reason, the employment certificate should always be issued for a particular job, and should be issued in the name of the employer. No new certificate should be issued unless the child has had a physical examination and is shown to be in sound health, and physically fit to perform the work he intends to do. Repeated physical examinations of this type will, in time, show the effects of various industries upon the health of children and will, in the meantime, protect the child to a very great extent from entering an industry that may have a serious effect upon his physical well-being.

When children are continuously employed in any position for more than one year, provision should be made for yearly physical examination of each child. Such examinations might well take place in the industrial plants or at the office of the official who issued the original employment certificate. If carried on in the industrial plant, it might easily be part of a general program for industrial hygiene and as such offers an opportunity in a field which has hitherto been neglected.

Minimum Standards of Fitness

No child should be allowed to go to work unless he is in sound physical health and physically fitted to perform the work he intends to do. "Sound physical health" should here be interpreted in a literal manner. Deviations from the physically normal may not seem to be either a symptom or a cause of ill health, but the future consequence of such physical defects may easily be serious enough to form a definite handicap to proper physical development.

The type of defects for which men were rejected in the draft were those which are commonly encountered in children applying for employment certificates. If 39 per cent of our young men between twenty-one and thirty-one years of age were rejected in the draft because of these prevent-

able and easily remediable physical defects, it is a clear indication that the ultimate injury resulting from such defects warrants more serious consideration during the period of childhood than any we have ever given before. Practically all these defects begin in early childhood. If neglected during the school age, they may establish abnormal physical conditions which will be permanently harmful. If they still exist at the time the child reaches the stage of adolescence and wishes to go to work, the final opportunity is presented for correcting them before they do definite harm. For these reasons, every child who wishes to go to work should be subjected to a thorough physical examination. It is probable that the Committee on Standards of the Children's Bureau will recommend a definite form of examination, standardized so that there can be no question as to its thoroughness. At this time it is sufficient to say that any examination of the child before he enters industry should cover the following points: height, weight, general physical conditions, condition of nutrition, maturity, examination of the skin, eyes, ears, mouth, nasopharynx, glands, heart, lungs and abdomen. Orthopedic defects should be noted, and diseases of the nervous system and disturbance of the menses are also of importance.

The standards of height and weight which have been used by the Department of Health of New York City for a number of years are:

Fourteen years...58 inches...80 pounds
Fifteen years...58 inches...85 pounds
Sixteen years...59 inches...90 pounds

No difference has been made in the requirements for height and weight of boys and girls because it has been felt that while boys may be noticeably taller and heavier than girls, the latter are entitled to greater protection. Their standards, therefore, have been made as high as those for boys.

When a child is found to be 10 per cent below the proper weight for his height, he should be examined by two physicians to determine whether this underweight is the result of undernourishment or other bodily defect or whether it is a racial or family characteristic. In the latter case, of course, there may be no physical disability and if the child is found to be otherwise in good condition, the employment certificate may be issued.

It has been found that certain types of physical defects may be easily remedied, and if we are to issue employment certificates at all, it hardly

seems fair definitely to refuse a certificate to a child who could be put in sound health with a reasonable amount of care. Such cases, therefore, are classed as having the certificates "temporarily withheld" and only where treatment is not obtained after a reasonable length of time is the certificate refused permanently.

The opportunity for affording proper health supervision and adequate treatment to the children who are found to be physically defective is one of the most important results of physical examination. The standards and methods carried out in New York City may be taken to indicate what may be considered the minimum for any state that wishes to prevent the employment of any child who is physically unfit. The standards brought out by New York City have recently been adopted by the rest of New York state.

Physical defects which justify permanent refusal are: (1) cardiac disease; (2) tuberculosis or other evidence of serious pulmonary disease; (3) tuberculous or syphilitic disease of joints and bones; (4) irremediable defective vision; (5) trachoma; (6) serious orthopedic defects; (7) malnutrition, equivalent to Grade 4 of the Dunfermline scale; (8) chorea; or (9) total deafness.

Every effort is made to see that children who are refused employment because of physical defects are referred to some appropriate person or agency for whatever medical or other assistance is needed.

Temporary refusal is based upon the following defects: (1) Defective vision subject to correction by lenses; (2) contagious eye and skin diseases; (3) defective teeth: extraction or treatment needed; (4) malnutrition, equivalent to Grade 3 of the Dunfermline scale; (5) untreated hernia; (6) hypertrophied tonsils, where there is evidence of serious obstruction or diseased condition; (7) defective nasal breathing, causing complete occlusion of the nostrils; or (8) tuberculous glands.

All children who are temporarily refused employment certificates because of the existence of physical defects which may be curable under proper treatment, are referred to the care of the school nurse of the Bureau of Child Hygiene, who assumes responsibility for the case and makes every effort to see that the necessary medical treatment or other care is secured for the child. When such care has been provided and the physical defect has been corrected, the employment certificate is issued.

In diagnosing malnutrition, weight in relation to height, and both in relation to age, are taken into consideration as one of the factors. The same qualifications noted under "minimum standards of height and weight" are applied in this connection. Children who are 10 per cent below the minimum weight for their height and age must be examined by two physicians to determine whether or not the underweight is the result of individual or racial characteristics or whether it is due to some undernourished condition. It is realized that undernourishment exists in varying degrees. The Department of Health of the City of New York has for many years classified cases of undernourishment according to the Dunfermline scale.

This scale recognizes that there are certain indications of undernourishment other than insufficient weight in relation to height. The facial expression of a child, the presence of dark circles under the eyes, look of extreme fatigue, evidences of anemia, flabby muscles, slouchy position, hollow chest, winged scapulæ and other indications of a loss of physical tone, are all taken into consideration. The degree of undernourishment is indicated by using the Dunfermline scale, as follows:

(1) *Excellent*.—Indicates that the child is in splendid physical condition and absolutely sound health.

(2) *Good*.—Indicates that the child falls below the standard of "excellent" yet does not show any definite signs of undernourishment.

(3) *Needing health supervision*.—Indicates that the child shows definite signs of undernourishment and needs health supervision.

(4) *Needing medical care*.—A child in this grade is in an advanced stage of undernourishment and should be under medical care.

The application of such standards to New York City has resulted, in the year 1919, in the absolute refusal of 3.17 per cent of all children who applied for employment certificates, on the ground of physical defects. During the first three-quarters of 1920, of the total number of children who applied for employment certificates, 3.15 per cent were refused because of physical defects. These figures, of course, refer only to children who have defects which cannot be corrected. The children who have defects which may be easily remedied are, in most instances, given their employment certificates eventually and do not enter into this calculation.

In this connection it may be of in-

terest to state that during 1919, 49,294 employment certificates were granted and 2,306 were refused. By far the greater number of these were refused because of physical incapacity (1,668). The other classifications were insufficient tuition, 44; insufficient education, 10; under age, 27; over age, 557. An analysis of the causes of rejection for physical incapacity shows the following:

	Per Cent
Malnutrition	9.65
Cardiac disease	20.26
Pulmonary disease	1.08
Defective teeth	30.50
Defective vision	16.42
Adenoids and enlarged tonsils..	9.60
Miscellaneous defects	12.39
Total	100.00

In determining the physical status of the child, certain other items must be taken into account. Race and na-

tionality, age and sex, as well as family history, have a marked bearing upon the matter. For the purpose of determining the child's fitness to be employed, the intended occupation should always be ascertained.

While future study is necessary, if we wish to determine whether children who are only partially physically disabled may go into certain types of industry, for the present, at least, if we are to afford full protection to our children we must consider that no child who is physically abnormal should engage in any gainful occupation whatsoever. Such a standard is not impossible of achievement. It has been successfully maintained in New York City for a number of years. Even this, however, is not the goal towards which we should be working. From the point of view of the eco-

nomie status of adult labor, the serious effects of lack of education or illiteracy and the lasting harm that may result from industrial employment of children during the period of adolescence, it seems that, in this country at least, the arguments against the employment of children far outweigh any advantages that have been mentioned in its favor. The experience of twenty years in close relation to this subject has convinced me that child labor is neither necessary nor desirable, that it may have an exceedingly harmful effect upon the physical development of children and that the employment of any child under sixteen years of age should be prohibited. Surely, this great and rich nation does not need to live on the earnings of its young.

The Industrial Surgeon and Individualization

BY RALPH B. BETTMAN, M.D., CHICAGO

AS industrial medicine continues to develop it is found that more and more diseases come under its scope and instead of being confined to traumatism, lead colic, and chemical dermatitis it is gradually embracing a very large field. A physician engaged in industrial medicine is confronted with a variety of problems about which his medical brother who is not dealing with industrial groups knows little. The etiology and symptomatology may be different and the treatment even more so.

The laboring man depends for his existence on the time he can work. Unlike the average business man, a lay off means instant loss of revenue. Stock dividends are not coming in to help buy the groceries; there are no well filled shelves of merchandise, the sale of which brings in funds to clothe the family. Every hour lost is an item on the debit side of the ledger. The industrial surgeon must constantly keep this in mind and adapt his treatment accordingly. There are numerous occasions where the length of the period of total disability can be greatly reduced. Or an operation may be definitely indicated which in a patient belonging to a different group might be postponed or entirely supplanted by medical treatment. For example, an operation for a gastric ulcer would well be employed much earlier in the case of a man whose weekly pay envelope is a matter of prime importance than in

the case of a patient who can afford a protracted course of medical treatment.

Again, it may be wise to counsel against certain operative interference and resort to temporizing methods. A worker engaged in a sedentary position may be able to postpone indefinitely an operation for an inguinal hernia, wearing, if necessary, a truss. A buttonhole maker would feel no ill effects from a hernia while in a presser, who must use a heavy iron, would require operative relief. In timing an operation of choice the economic conditions play an important rôle. In some instances it is wise to delay until such a time when the worker may be out of employment due to the seasonal layoff, or an operation may be hastened to permit the patient to be ready for work when an expected "rush" will result in overtime and the concomitant increase in pay.

Not only in the larger problems, but in the smaller details has the industrial surgeon a chance to help keep the patient as a wage earner in spite of his illness. A very small bandage for a cut finger may enable a stenographer to remain at work, while a very large bandage for the same condition may afford the necessary protection so that the freight handler will not "lose time." A sales clerk can not work with an unsightly dressing, while a man exposed to grime and dirt may need a large dressing to prevent contamination.

In short, the industrial surgeon must continually bear in mind the economic condition of his patient; he must realize that the time element is a most important one, he must question every procedure to assure himself whether it could be substituted by some other method which would shorten the time of disability. As Robert Osgood most aptly put it recently, "the importance of gaining the largest amount of function in the shortest possible time is paramount."

Labor Office Reports on Lead Poisoning

The International Labor Office issues in its Legislative Series a British Act to make provisions for better protection of women and young persons against lead poisoning, dated the 23rd of December, 1920. According to the Act, it is not lawful for any person to employ women or young persons on work at a furnace where the reduction or treatment of zinc or lead ores is carried on; the manipulation, treatment or reduction of ashes containing lead, the desilverizing of lead, or the melting of scrap lead or zinc; the manufacture of solder or alloys containing more than 10 per cent of lead; the manufacture of any oxid, carbonate, sulphate, chromate, acetate, nitrate, or silicate of lead; mixing or pasting in the manufacture or repair of electric accumulators; the cleaning of workrooms where any of the processes aforesaid are carried on.

The Housing of the Unskilled Wage Earner

STANDARDS as observed in the United States for the housing of wage earners are the subject of a recent study by Edith Elmer Wood. One of the incidental benefits of the war was that it awakened us to the importance of housing. "No nation can rise higher than the level of its homes. Whether we approach the subject from the point of view of health, morals, child conservation, industrial efficiency, Americanization, or good citizenship, the housing problem is fundamental." A place to live in is as important as a place to work in, and, if people are to work efficiently and well, they must have real homes to go back to when the day's work is done,—not simply a roof and a bed. It is the purpose of this book, as explained by the author, to afford a basis of authentic facts on which to develop a comprehensive housing policy and for the critical interpretation of the facts. American as well as foreign housing standards and conditions are discussed and criticised as to their shortcomings and successes; the various methods for meeting the situation and the extent of success and adaptability of the foreign schemes to our own conditions are fully analyzed.

It is estimated that about one-third of the people of the United States are living under subnormal housing conditions; that is, which fall below the minimum standard developed later, and about one-tenth are living under conditions which are an acute menace to health, morals, and family life, conditions which tend to produce degenerative changes in those subject to them.

Certain minimum standards of floor space, window space, cubic air space per occupant, size of courtyards, plumbing, fire escapes, repairs, and cleanliness, have been enacted into law, but until 1895 the Trinity Church Corporation fought the provisions of the New York Tenement House Act of 1887 requiring running water on each floor of a tenement house. The question as to whether a bath tub is a luxury or a necessity is still undetermined.

The housing problem may be stated briefly in two ways: how to avoid bad houses and get good houses, or how to get good houses and avoid bad ones. This is the positive or negative approach to the situation result-

ing in the two types of law; the constructive type which aims to increase the supply of good houses, and the restrictive type which seeks to prevent the erection or maintenance of bad houses, through the establishment and enforcement of minimum standards of light, ventilation, sanitation, and safety. Both, of course, are essential to a well rounded policy, but a high standard of restrictive legislation will not be enacted, or if enacted will not be enforced because of the resulting house famine, the only alternative being a relaxation of standards. The housing problem is two-fold and must have a two-fold solution: houses must not be built or occupied which fall below an accepted standard, and enough houses must be built in conformity to supply the demand.

There is no question, according to the author, about the possibility or rightness of a solution, "the housing problem *must* be solved. . . . If we were not utterly blind and heedless, we would go to any length, make any sacrifice to enable every child to spend his first five years, at least, while the foundations of his health, his mind, and his character are being laid, in the environment of pure air, sunshine, cleanliness, and serenity."

There is a very full discussion of the housing conditions in the United States, a history of housing in New York, tracing the various investigations and suggestions offered for solution. Washington, Boston, San Francisco, Baltimore and others are shown not to be without fault. The legislation developed, the Vieller Model Housing Law, the Tenement House laws and Administration in New York and other states; and city legislation are all considered. The Vieller Model law and the administration of the New York Tenement House Department are said to be the best contributions yet made in the United States to the housing experience of the world. Modern housing under private or corporate initiative is developed, but, as is pointed out, philanthropy can set standards but cannot supply the demand for cheap and wholesome homes for workingmen. Housing by employers sometimes provides satisfactorily for health and comfort, sometimes not. It is at best a makeshift and will never furnish the final solution unless we go back to feudalism. "The instinct of the workingman who dis-

likes the company house, the company school, the company store is sound. The system is undemocratic, un-American, and the workingman who accepts it gives up a considerable share of his independence."

A Real Shortage

There are housing conditions not only in the United States but universal in character which should not be tolerated in any civilized community. "The fundamental trouble is the scarcity of wholesome houses of an acceptable standard at a low enough rental for the rank and file of unskilled wage earners." The methods tried in this country have been tried in Europe. The state as well as the city has undertaken to supply houses; loans are made to non-commercial housing companies; to individual workers, and tax exemptions are granted. England has been one of the pioneers in this field. Belgium, France and Germany have all followed suit, as well as other European countries, South America, and Cuba.

The work of the Massachusetts Homestead Commission, the Oklahoma loan experiment and town planning legislation is reviewed. American cities on the whole, however, have paid comparatively little attention to housing as a part of their comprehensive city plans. The building and loan associations have been a great force in America and the whole system with government aid in the form of loans, given only to those associations which met specified requirements might well be adapted to fit the needs of unskilled labor.

In spite of the constitutional and other objectives to the policy of constructive housing legislation, there seems to be no insuperable object "if and when the people decide they want it." The author proceeds to develop an outline of a comprehensive housing policy for the United States based upon suggestions and observations recommending both restrictive and constructive legislation, national, state and local, which would involve a national housing commission, postal saving deposits, loans to individual workingmen and housing loans by national banks and other measures.

In the last analysis, the housing of the unskilled worker is America's next great problem, the one to determine our progress or decadence. With housing as it is in many places today the health of the nation is impossible.

Health Measures at Culver Military Academy

The Quick Reaction Time in Athletic Games Serves Well in Other Crises

BY L. R. GIGNILLIAT, COLONEL, U.S.R., SUPERINTENDENT, CULVER, IND.

IN THE care of the health of the student body at Culver, prevention is the thing. In the first place, the sanitary conditions into which the boy is invited are carefully planned, and constantly supervised. The buildings are modern in every respect, although the quarters are not elaborate or luxurious. Much attention is given to the careful and thorough ventilation of dormitories and class rooms. The water supply is abundant and easily accessible, and safeguarded to the last degree against contamination. Frequent analyses are made to insure against possible pollution. In the more than twenty-five years of the school's history, there has never been a case of typhoid fever which developed on the grounds.

The care and preparation and serving of the food receive more than ordinary attention, and on more than one occasion Culver has received the highest commendation from experts in such matters. Dr. E. C. Rosenow, in reporting on the inspection made of these conditions, stated that in his wide experience he had never seen a food supply handled so efficiently and satisfactorily from the sanitary standpoint as at Culver.

Examined and Re-examined

At the beginning of each term each cadet is given a thorough medical examination immediately on his arrival—first, to make sure that he is not bringing into the institution any contagious or infectious disease, and second, to determine whether or not

he is physically able to carry on the work prescribed. A second examination is made after a lapse of two weeks, which is a sufficient time to cover incubation period of practically all infectious diseases. This physical examination is required after the Christmas recess, as well as at the time of entrance. Coincident with the medical examination, careful observation is made of any malformation or deficiencies of development which may be capable of correction by physical exercise, and when such defects are found, the cadet is assigned to appropriate corrective work under instructors in the physical department. The accompanying photographs of the correction of faulty carriage illustrates to some extent what may be accomplished in this direction. Care-

The Academy is located on one of the larger lakes of northern Indiana, with extensive immediate grounds, and surroundings which promote outdoor activities.

The benefit of competitive vigorous athletic games is not confined to a few, but is universally enjoyed.

In order to prevent sluggishness between class periods group calisthenics are employed in the form of setting up drills which react favorably on instructor and pupils.

The supervising surgeon sees to it that none takes part in the more strenuous contests who is not physically fit. Individuals with defects or inherent weaknesses receive specific exercises.

ful records of all these examinations are kept and are available at any time, and serve as a guide to the boy's physical development, and a check, if needed, to his athletic activities. All forms of athletics are encouraged, but over-athleticism is not only discouraged, but is dis-allowed. No cadet may enter athletic practice without the approval of the school surgeon, nor may he participate in any athletic contest without adequate preliminary training under the supervision of an experienced coach. Overstraining of the heart and general physical exhaustion are prevented by this rule. Some accidents, of course, happen to players in any of the more vigorous forms of sport, but it has been our experience that practically all of the more serious accidents have occurred during unsupervised play.

Athletics, as a factor in health and in general development, seem to us to have such great value that every boy is urged to participate regularly in some form of athletic activities, and on at least one day each week, the military drill gives place to required athletic work. A recent canvas of the cadet corps of seven hundred boys showed that all but six were participating in voluntary sports. It has been our observation that, as a rule, reasonable regular activities react favorably not only on the health of the cadet, but on his academic record as well. In the arrangement of the academic work, there are six class periods between breakfast and dinner. In order to prevent sluggishness in the latter periods, we inject a short period of calisthenics and setting up drills, out of doors on the parade grounds unless prevented by stormy weather. This allows a thorough ventilation of the class rooms, stimulates the physical and mental activity

of the boy, and by the method employed, develops team work and co-operation between the members of the corps. This break in the program undoubtedly reacts as favorably on the instructor as on the student.

The Academy is most favorably located on the shore of one of the larger lakes of northern Indiana. The immediate grounds are quite extensive, and around it lies a very interesting country, a combination of conditions which provides an unusual variety of sports. At the proper season the boys enjoy swimming in the lake, but this also is under strict supervision. During the winter months the sport is enjoyed in the exceptional indoor pool. Here again,

the best of sanitary conditions are assured through continuous filtration and through the sterilization of the water by the ultraviolet ray.

Surgeon in Charge

Of course we maintain a small hospital or infirmary. A surgeon in charge has supervision, not only of this hospital, but of all the sanitary conditions and physical activities. His immediate force consists of an assistant surgeon and two graduate nurses. This force is supplemented as may be required.

Before breakfast each morning a sick call is held at which time any cadet who is indisposed reports for proper attention. Inasmuch as no

What appropriate corrective exercise may do for faulty carriage is well illustrated in this serial record of actual work done. Parallel records are kept which serve as a guide to the boy's physical development and, if need be, as a check to athletic activities.

No cadet undertakes athletic practice or enters any form of contest without adequate preliminary training under an experienced coach.

The location of the Academy favors a wide variety of sports. Winter is not an indoor season here.

one else on the grounds is authorized to excuse any man either from academic or physical duties, it follows that even slight illnesses come to the surgeon's attention in their incipency. In the event of the development of any contagious disease, prompt isolation is thus possible, and epidemics of serious proportions have not occurred except during the prevalence of influenza three years ago. Even here our experience was most fortunate. There were one hundred fifteen cases, but because of the promptness of recognition and hospitalization, we had not a single fatality nor a case of pneumonia complicating the original disease. Last year with the incidence of scarlet fever, the initial cases were in a hospital for slight malaise before the development of the characteristic symptoms. Not only were these cases and their room mates isolated, but there was instituted a daily inspection of every member of the corps. As a result the number of students infected was limited to twenty-three, five of these cases de-

ected on inspection were so slight that the boy was not conscious of any ill-feeling, but had a faint, though characteristic rash, the subsequent course of the disease verifying the diagnosis. Such slight cases are recognized by medical authorities as one of the most common means of the extension of an epidemic.

Our students are encouraged to report to the medical officers even trivial injuries or ailments, as they might eventuate in serious conditions. Attention to apparently insignificant conditions takes time and is at first thought expensive, but our experience has justified the expenditure of both time and money, and has commended itself to a clientele of thinking men throughout the country. We have known that our methods are somewhat unusual, but we had not considered them particularly remarkable until last year after our surgeon accompanied the group of three hundred American Boy Scouts to the International Jamboree in London and through France and Belgium, and on

the tour applying the same methods. The Surgeon General of the United States, learning of the health record of the boys on this trip, concluded his official record of the matter as follows: "This ideal record of handling and preventing communicable diseases demonstrates the results that may be attained by careful and thorough physical inspection . . . by detailed attention to cleanliness, and by prompt segregation and treatment of all conditions which may, perchance, be the initial symptoms of an acute infectious disease. The medical officers charged with the supervision of the health of this group of boys, are to be congratulated on ideal results accomplished."

The prevention of the introduction of infectious diseases, together with the régime instituted to build up the boy's physique and to increase his natural resistance to disease, has given Culver a health record second to no institution in the country, and has been a large scale health demonstration.

Standardizing Tuberculosis Work

Attempt is being made to standardize the tuberculosis work of all relief giving agencies in St. Louis. Because of the frequency of tuberculosis among families for which "question as to the adequacy of treatment given such families has been a constant source of discussion," a questionnaire covering the medical, social, and economic and legal problems involved, as well as the plan for reconstruction, was sent out by the Tuberculosis Society of the St. Louis Social Service Committee. As a guide to similar studies this questionnaire is published in the April issue of the *Bulletin* of the National Tuberculosis Association.

A group of tennis enthusiasts. A recent canvass of the cadet corps of seven hundred boys showed that all but six are participating in voluntary sports.

The University of Michigan Health Service

BY WARREN E. FORSYTHE, M.D., DIRECTOR, ANN ARBOR, MICH.

IN 1912 a well known student at the University of Michigan escaped from a local hospital during the delirium of pneumonia, and was found dead in the Huron River. While such accidents are not unknown to most general hospitals, the reaction upon the campus following that occurrence doubtless added much weight to the demand for a student health organization at this university. This was established in October, 1913. As at many other places, the organization here has been able to progress but slowly from the limitation of a student infirmary into the important fields of disease prevention and health promotion. The department had scarcely started to function, however, before the name of University Infirmary was replaced by the more ambitious title of University Health Service.

In cooperation with the departments of medicine, the Health Service has from the outset provided good service to sick students. Subsequent extensions have carried its influence into the realm of health conservation. This is a phase of public or group medical work rather recently but widely established in American colleges and universities. A bibliography of about sixty papers concerning student health work directly was recently compiled.¹

How Administered

The Health Service is an activity of University Administration. It is headed by a full time physician as director, and since 1916 its policies have been determined by the Board of Regents, without a faculty committee. The personnel at present consists of six full time general physicians, a pharmacist, two nurses, and three office assistants. Additional assistance is employed when needed, as during the examination of new students at the opening of the school year. Most of the hospital attention and consultation is provided by specialists of the medical schools in the University teaching hospitals, and the expense of such service is provided for by the Health Service budget. The physicians' salaries range from \$2,500 to \$5,000 for twelve months service.

While the scope of the Health Service is being gradually extended beyond the care of the sick and injured, it has as yet little control over athletics, physical education, and the

The Health Service Staff of the University of Michigan, 1920-21.

sanitation of the student's environment.

The work of the Health Service is supported entirely by a portion of student fees. Until 1917 the fee was \$4.00 per student annually, collected and dispersed by the University as

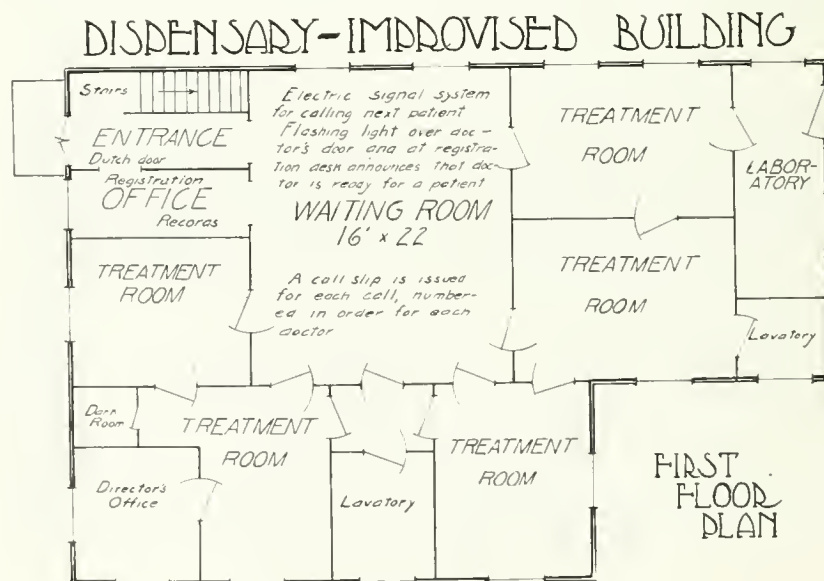

for other departments. The fee was increased to \$6.00 at that time, and the fees have supported the work.

The medical service to which a student in the University of Michigan is entitled for the fee paid is equaled in few if any other education institution in the country.

Medical Examinations.—Upon entering the University, all students receive a very complete medical and physical examination. The unprotected are vaccinated unless excused by the Director. A letter is written to the parent, stating the conclusions and advice resulting from the examination, and announcing Health Service privileges. The examination records are arranged upon a large folded card which is used for reference and as a folder for all subsequent Health Service records of that student. Starting this year with one additional class each year, a re-examination will be required of all upper classmen annually.

Health Instruction.—Freshmen are required to attend a series of six health lectures early in the year. This is inadequate and will probably soon be extended to a semester course.

Dispensary.—A Health Service dispensary is located near the campus and open five hours daily. Here students may receive promptly, unlimited office attention free, including x-ray examinations, drugs, dressings, vaccines, antitoxins, minor operations and refractions. Glasses are

Hospital attention and consultation are provided by specialists of the medical schools in the University teaching hospitals.

1. American Students Health Association, 226 Ingalls St., Ann Arbor, Mich.

2. Emerson, Haven, M.D.: Education in Health at Cornell University, Am. J. Pub. Health, April, 1921.

provided at moderate prices. Complete records of each patient are kept as well as data for general use.

Room Calls and Epidemiology

Calls are made and students are cared for in their rooms when hospitalization is not demanded. This is often not so much from choice as because of the crowded condition of hospitals available. The department receives credit for small fees collected by the University for room calls. The number of such calls is not large.

One member of the staff serves as epidemiologist and supervises contagious diseases and their control. Such cases including acute tonsillitis are reported to him at once by other physicians.

Hospital Care—Because of fortunate cooperation with the teaching hospitals of the medical schools, the Health Service is able to provide the student complete hospital care free up to a limit of sixty days each year. Such care is generally limited to emergency operations and conditions which menace the immediate health of the student. Elective operations are not so considered, except in individual cases of self-supporting students. Staff physicians keep in touch with hospital patients and send reports to parents and interested faculty members.

Other Services.—A staff physician has charge of the health of the students at the summer school camps of engineering and biology located in another part of the state. Our physicians attend athletic games, and in numerous other ways render service to students directly and in cooperation with other members of the University. Athletic injuries are cared for by the Health Service the same as those resulting from other causes.

Results Are Tangible

The question naturally arises: What tangible results can be shown from seven years' experience of such an organization? A general decline in dispensary calls per 1,000 enrollment since the work was well established is our best numerical fact. Not long ago the President of the University expressed the opinion that student illness had decreased and that attention to it had given the administration little concern since the organization of the Health Service.

Several factors, such as no records prior to 1913, variable popularity of some features of our work, and war conditions, cause us to hesitate as yet in drawing conclusions from much of our data.

A reduction in numbers of calls and

patients in itself may mean either a reduction in disease rate or an inferiority of service rendered. We believe that the former is the case here as there is no evident increase in student patronage of local physicians, with whom our relations are most cordial. Local physicians may make use of any of the Health Service facilities and privileges in the care of their student patients when a member of our staff, in a position of consultant, is able to approve of the expenditures involved.

While our organization and its work are far from perfected, we feel that students here receive medical attention which approaches the ideal, and at a small expense equalled in very few, if any, comparable communities or groups.

We feel that our statistics should be of interest not only for comparison with those of other colleges and universities, but as standards for any group of similar ages, and we are aware of our opportunity to work out and determine much that will have application to group medical work in general. The development of an adequate group service anywhere depends upon a candid and complete statement of the problem. The best basis of future expansion is scientific analysis of records. Conclusions so reached have a definite value and a very wide application. There follow herewith, condensed tabulations and charts to illustrate various phases of common disease incidence and other features of our experience.

Annual Averages

From the records of seven years, the following annual averages of various items are given in terms of 1,000 students enrolled, (Tables A and B).

Staff earnings result from room call charges and from a small profit upon the sale of glasses. Hospital expense is low because of no overhead. It has averaged about \$3.25 per day per patient. Many cases would not be kept in their rooms as at present, if hospital space were available. A new hospital is being built, which, when completed, will provide ideal facilities. The general death rate in the United States for the age group 20 to 24 is about 5. The figure for major operations does not include electives as for hernias, chronic tonsils, deviated septa, etc.

Acute gonorrhea for the entire student body this year amounts to about 7 per 1,000 enrolled, and syphilis is probably not over double the figure given for our records.

TABLE A.—MISCELLANEOUS DATA PER 1,000 ENROLLMENT, ANNUAL AVERAGES.

Expenses (net means deduction of staff earnings):	
a. Salaries and wages (net).....	\$1,975
b. Current expense	420
c. Hospital care	1,200
d. All service (net).....	3,342
e. Staff earnings	187
Other data:	
a. Dispensary calls	3,157
b. Number patients	543
c. Room calls	82
d. Hospital patients	35
e. All deaths at University and elsewhere	1.13
f. Major operations	6

TABLE B.—SELECTED DIAGNOSIS PER 1,000 ENROLLMENT, ANNUAL AVERAGES.

Appendicitis, acute	6.0
Bronchitis, acute	28.0
Chickenpox	0.7
Diphtheria	1.0
Fractures	4.0
Furunculosis	27.0
Gonorrhea	3.0

Laryngitis, acute	21.0

Comparative Annual Incidence

From seven years' records also, we give charts A and B together with Table C to show *annual changes*. For the remainder of 1920-21 after

CHART A.—GENERAL DECLINE IN DISPENSARY CALLS.

April 1, estimates have been made. The difference shown between the records for the war years, 1917-18 and 1918-19 is probably exaggerated

CHART B.—GRAPHIC RECORD OF CONTAGIOUS DISEASES. CHARTS A AND B WITH TABLE C SHOW ANNUAL CHANGES.

owing to uncertainty of actual university attendance. The general decline in dispensary calls as shown in chart A may be fairly interpreted as reduced illness among our students.

the months of the year. Curve A in Chart C shows dispensary calls as influenced by the medical examination of new students during October and by the vacation periods. The curve B

TABLE C.—COMPARATIVE ANNUAL INCIDENCE SELECTED DIAGNOSIS PER 1,000 ENROLLMENT.

	13-14	14-15	15-16	16-17	17-18	18-19	19-20	20-21
Rhinitis, acute	101.	137.	115.	112.	177.	80.	131.	151.
Appendicitis, acute	5.	7.	7.	7.	5.	4.	8.	4.
Tuberculosis, active	2.	2.	7.	3.	1.	1.	2.	2.
Furunculosis	16.	23.	23.	16.	30.	24.	43.	40.
Gonorrhea	3.	6.		2.	2.	2.	1.	2.
Syphilis	1.	1.7	1.	.4	1.5	.16	.17	.37
Local infections	14.	15.	9.	13.	42.	20.	37.	40.
Tonsillitis, acute	70.	65.	48.	55.	97.	38.	32.	26.
Sinusitis	4.	6.	8.	5.	5.	4.	7.	7.
Typhoid	0.	0.	.16	2.1	.6	0.	.11	.37
Influenza	0.	0.	0.	0.	70.	33.	52.	0.
Scabies	2.	1.	2.	.4	2.3	4.6	8.	5.
Impetigo cont.	3.	2.4	2.6	2.3	4.	2.8	3.4	4.7
Tinea cruris	2.7	1.	6.	1.5	2.	3.8	6.3	10.
Otitis media, acute	4.8	2.6	8.5	4.2	4.	1.6	2.	1.6
Laryngitis, acute	26.	15.	19.	30.	41.	8.	26.	9.

In Table C, one notes the decline of venereal disease, tonsillitis and acute otitis media. In the same table we find that furunculosis, local infections, scabies and tinea cruris have increased. The diseases included in chart B are for the contagions; measles, rubella, varicella, variola, and scarlet fever, and for acute respiratory infections: rhinitis, tonsillitis, pharyngitis, bronchitis, tracheitis, sinusitis, laryngitis, nasopharyngitis, grip, pneumonia, and influenza.

CHART C.—GRAPHIC RECORD OF DECLINE IN VENEREAL DISEASES, TONSILLITIS, AND ACUTE OTITIS MEDIA.

CHART D.—CONDENSED RECORD OF APPENDICITIS INCIDENCE.

Seasonal Disease Incidence

From four years condensed records, we present Charts C, D, E, F, and Table D, concerning the average occurrence of common diseases during

shows the estimation of probable calls without those two influences.

TABLE D.—SEASONAL DISEASE INCIDENCE.

	July	Aug.	Oct.	Nov.	Dec.	Jan.	Feb.	Mar.	Apr.	May	June
Sinusitis	1.	.6	4.2	2.3	3.6	7.5	9.7	11.	3.	4.3	.12
Measles & Rubella	0.	0.	0.	.25	.5	4.25	6.	6.	3.	7.	0.
Diphtheria	.6	0.	.6	0.	1.	.8	.25	1.2	1.3	.3	.3
Infections, local	10.3	5.6	30.2	27.	22.7	39.2	31.	31.7	25.	30.	19.6
Furunculosis	9.	6.	39.7	37.	27.7	37.2	26.2	35.	18.	26.	13.

We have nothing to suggest as to the cause of the form of the curve in Chart D, and it is difficult to say just what factor in the life of students causes the most decline in skin contagions during the college year.

In Table D, one notes the comparative lack of seasonal influence upon furunculosis and local infections.

From our experience, we may conclude that women are more susceptible to the acute respiratory infections than are men students (Chart G). This is in accord with recent reports from Cornell University.³

Other Considerations

To determine days of most calls, we have arranged our daily dispensary records for a typical year (Chart H).

From four years' records of about twelve cases annually, it appears that active pulmonary tuberculosis develops in order of frequency in the following departments: Dental, Medical, Engineering, Law, and Literary.

Conclusions

(1) Judging from the experience at this university, the demand for attention to sick and injured students will be the main influence in starting student health work elsewhere.

(2) Experience in organization here

CHART E.—SKIN CONTAGIONS GRAPHED BY MONTHS.

has justified an independent department, a small board of administration, a full time personnel, a broad policy in relation to local physicians in the care of sick students, support by a general student fee, freedom in student choice of physicians, and the development of preventive medicine and health promotion.

(3) From among results obtained we conclude that student illness has

been reduced; that medical attention has been furnished such as would not have been obtained otherwise by the majority of students; that the general fee has been a burden to none and has resulted in a blessing to many.

(4) From student health work in general we conclude:

(A) Active progressive health work among students in colleges and universities is well established and of importance for the following reasons: (a) It meets the obligation of the university to care for illness, prevent disease and promote health among students. (b) It has great educa-

CHART F.—INCIDENCE OF RESPIRATORY INFECTIONS.

tional value in giving students experience with medical service under the

best conditions and should influence them to promote such health work in the communities to which they return.

CHART H.—DAILY DISPENSARY RECORDS.

(5) Health departments in educational institutions have splendid opportunities of solving problems, developing methods, and setting stand-

ards for future community medical work.

Laboratory Association Formed

There was organized in Atlanta, Ga., March 16, the Southern Health Laboratory Association, which is the first association in the United States of public health laboratory workers for the purpose of securing uniformity of methods and procedure among the public health laboratories of the Southern states. Representatives of health departments in seven southern states were present and the following officers were elected: President, Dr. Clarence A. Shore, Raleigh, N. C., and secretary, Mr. T. F. Sellers, Atlanta.

Therapeutic Achievement With Radium

MUCH recent interest has centered about the subject of radium, the rare metal which is so full of potentialities, and which is so rare and precious that disputes have arisen concerning what uses are the most profitable for the small amounts available, and whether proportionately large amounts should be devoted to ultrascientific research of remote application to industrial and medical problems.

A peculiar fitness attached to the gift of a gram of radium to Mme. Curie in her recent visit to the United States, the French scientist who first isolated and named the metal.

Formerly the world supply of radium came from the pitchblende of Bohemia, where it occurs in pockets in widely separated localities, so that

no steady supply could be assured. Recent discovery of relatively abundant deposits in Colorado and Utah promises to remedy this condition to some extent. Its price cannot be greatly reduced, however much may be mined, until the cost of its extraction and purification can be reduced.

The stimulation of scientific curiosity incident to the discovery of radium has resulted in an immense amount of research in many different directions. The release of energy in the process of its disintegration has suggested new and unlimited sources of power, the energy released in this disintegration of one gram of radium giving rise to fantastic theories of the possibility of releasing atomic energies in other or all elements for utilitarian processes.

Radium gives off three kinds of rays—Alpha, Beta and Gamma. The radium rays are electrical in nature,

International.
Apparatus employed in the Pasteur Pavillon, Paris, for the treatment of cancerous tumors by radio-active substances.

International.
The Institut du Radium de Paris, where Madame Curie conducts her researches on radium.

the Alpha, or positive ray, constituting about 90 per cent of the total emanations.

Only the Gamma ray is utilized in the treatment of cancer, as the Alpha and Beta rays produce untoward effects. Radium has been fully demonstrated to have reliable therapeutic uses. The Radium Institute of London has issued a recent report of successful achievement and an account of the best forms of apparatus and the technic which is calculated to use radium efficiently and economically and to prevent cumulative harmful

International.

Madame Curie, who first isolated and named radium, receives from President Harding a gram of the precious element as a tribute paid her by the women of America.

effects to those who constantly work with radium. They report a total of 822 cases of cancer seen for the first time during the year, of whom 22 were cured, 101 apparently cured, and 328 improved. The report emphasizes special points of merit which have been developed in American technic.

Research in this connection at Harvard University has led to the discovery by Dr. H. Duane of a more penetrating x-ray which will supplement work with radium on the alleviation of cancer at the Collis P. Hunt-

ington Hospital at Boston, an institution which is devoted to the work with x-ray and radium. Radium treatment of nerve tissue tumors is a noteworthy achievement.

While some complaint may come from scientific circles of commercial uses for radium, it is not to be forgotten that inestimable value attaches to the safety measures during the war made possible by its use. On the other hand, in the abstraction of the research laboratory which made possible the production of radium itself,

International.

Using electroscope for the measurement of radium from the vial containing radium.

its full contribution in therapeutic uses is yet to be worked out.

American Medical Association Elects Officers

The seventy-second annual session of the American Medical Association at Boston, just closed, was marked by the presentation of more than the average number of strictly scientific theses of great interest, and the discussion of medical service and the problems of the medical profession in the light of active public interest in health matters hitherto delegated entirely to professional initiative. Several of the leading addresses concerned themselves with phases of group practice, organization for health service, and the need of new ethics which would permit a more active leadership on the part of physicians in health matters and in educational enterprises for the benefit of the layman. While action on many matters was deferred to give opportunity for further investigation, the appointment of committees with powers to collect and report on the situation should crystallize opinion and make for leadership on the part of the profession.

The address of the incoming president, Dr. Hubert Work, was entirely concerned with the relation of the physician to the community and its problems.

Officers for 1921-1922 were elected as follows:

President-Elect—Dr. George E. de Schweinitz, Philadelphia, Pa.

Vice-President—Dr. Frank B. Wynn, Indianapolis, Ind.

Secretary—Dr. Alexander R. Craig, Chicago.

Treasurer—Dr. William Allen Pusey, Chicago.

Speaker of the House of Delegates—Dr. Dwight H. Murray, Syracuse, N. Y.

Vice-Speaker of the House of Delegates—Dr. F. C. Warnshuis, Grand Rapids, Mich.

Board of Trustees—Dr. Frank Billings, Chicago; Dr. Wendell C. Phillips, New York; Dr. Thomas McDavitt, St. Paul, Minn.

Judicial Council—J. N. Hall, Denver, Colo. (1926).

Council on Health and Public Instruction—Victor C. Vaughan, Ann Arbor, Mich. (1926).

Council on Medical Education and Hospitals—W. D. Haggard, Nashville, Tenn. (1926).

Council on Scientific Assembly—John E. Lane, New Haven, Conn. (1926).

Food Poisoning; Its Prevalence and Prevention

*Safe Measures Grow Out of the Pre-
cise Investigations of the Laboratory*

By JOHN PHILLIPS STREET, INDIANAPOLIS, IND., FORMERLY CHEMIST, CONNECTICUT AGRICULTURAL EXPERIMENT STATION, NEW HAVEN, CONN.

PRIOR to the passage of the Federal Food and Drugs Act in 1906, and in the years immediately following, the question of food adulteration was of vital import to the American people. Since that time, due to the activities of both Federal and state food authorities, food adulteration has become a matter of academic interest rather than one vitally affecting the health of our people. Sophisticated food, of course, is not entirely a thing of the past, but it is no overstatement to say that food adulteration that is injurious to health is practically nonexistent at the present time, and that such adulterations as do persist are of economic importance rather than a matter affecting public health.

Unadulterated food, however, is only one phase of the food problem. Perfectly good, nutritious, and wholesome food may go to the food manufacturer, and by faulty processes, slovenly methods and insanitary practices be rendered less nutritious and wholesome, or in extreme cases become absolutely dangerous to the consumer. On the other hand, food may be prepared commercially with every attention to sound raw material, proper manufacturing technic, and the best modern sanitary practice; it may leave the factory or packing house a safe and wholesome food in every particular, and yet be rendered unsafe and unwholesome by careless

Our chief health problems are man-made difficulties, growing out of the complex conditions of urban life. Not the least of these pertain to the transportation and handling of food.

Balanced diets for the whole people, and definitely prescribed rations for those whose nutritional needs are exceptional, are alike futile unless community efforts safeguard the food supply.

Food poisoning, therefore, should suggest forethought, not fear, and rigid inspection according to scientific standards to take care of the situation.

storage or handling in the institution, hotel, or private home where it is consumed. Such a condition is even more prevalent among "fresh" foods that go to the consumer in their natural condition or which undergo no manufacturing process. In fact, foods of this class are, generally speaking, by far a greater source of danger than processed foods, for the latter have usually undergone a cooking process that very greatly increases their margin of safety.

The Federal Meat Inspection Act practically assures the consumer that the meat he buys is sound, free from

pathogenic organisms, and is packed in a clean and sanitary packing house by clean workers, free from infectious or contagious diseases. Government inspected meat is sound and wholesome when it leaves the packing house, practically without exception, and in the transportation of the meat products from one state to another the Government still maintains a careful watch that the product on which it has placed its stamp of approval is not allowed to deteriorate during transit due to careless or unintelligent handling. Once in the local market, the responsibility for its proper keeping rests on the state or municipal authorities, and this responsibility is assumed with varying degrees of efficiency in different sections of the country, in the effort to force the wholesaler and retailer to maintain the excellence and wholesomeness of the product. When the meat is not Government inspected, where the product of local slaughter houses, inadequately supervised, is allowed to go into the market, there may be distinct menace to the health of the consumer. But no matter how much care is exercised by Federal, state or municipal authorities, the responsibility for the proper keeping and preparation of the meat in the home or institution rests very largely on the ultimate consumer.

Similarly, many safeguards are thrown around the production and

Keystone View Company.

The port of New York City is the largest receiver of foodstuffs in the world. Food inspectors are on the job twenty-four hours of each day as food is handled at the piers and terminals.

sale of milk. Unfortunately, however, raw milk is peculiarly liable to infection and in spite of official inspection, sickness due to contaminated milk is all too frequent. Here, again, all the advantage gained by official supervision of the production and handling of milk may be lost through improper care after it reaches the consumer.

In most of our progressive states sanitary codes are in operation which in a measure safeguard our food products during the various stages of manufacture and sale. There are so many food manufacturing plants, so many warehouses, so many shops, however, that proper official sanitary control of food establishments is almost impossible because of the cost involved. In this connection it is worth noting that certain industries have realized the importance of a strict sanitary control in their manufacturing processes, due in part to their appreciation of their obligation to the consumer to produce clean products packed by clean people in a clean factory, and in part due to their conviction that any food producer who is not willing to meet such requirements is a detriment to the industry and is entitled to no place in their councils or in their trade associations. The National Canners' Association, for instance, makes the qualifications just referred to essential to membership in its organization, and the statement, "Member of the National Canners' Association," on canned foods will possess increasing significance to the consumer as their ambitious project reaches its full development. The baking industry is contemplating a similar system of self-inspection, and more and more the

consumer is able to buy prepared foods with the assurance that the manufacturer has done everything in his power to render his product safe and wholesome and worthy of confidence.

Food Poisoning Defined

If one were to base his judgment on the sensational headlines of our newspapers it would be easy to believe that food poisoning occurs with alarming frequency, and that with each mouthful of food we run the danger of serious illness, if not death. The fact that the consumption of food has been an essential human function since man's creation, and the further fact that authentic cases of death from the eating of infected food or foods in which toxins are developed are so rare as to possess real news value because of their rarity, should give us some reassurance and help us to realize that the eating of our meals three times a day is not such a desperate gamble after all. However, it cannot be denied that people have died from eating tainted food, and that in some cases the fear of such a contingency has greatly decreased the sale of certain kinds of food, almost driving them from our markets.

To gain a clear understanding of this problem it is well to consider just what is meant by food poisoning, how food possessing poisonous properties can be detected, and what precautionary care is needed to prevent food from "going bad" or from developing toxins that render its use dangerous to health.

Food "poisoning" is perhaps an unfortunate and somewhat misleading term, but its use is so prevalent that

no attempt at more definite terminology will be made at this time. For the purposes of our discussion we may follow Rosenau's² definition and consider the term to cover acute illnesses due to some injurious property of the solid or liquid food consumed. Food may be injurious to health from various causes. The following is a condensation of Rosenau's summary:

(1) *Natural poisons*.—Some foods are poisonous by nature, as, for instance, certain mushrooms, some varieties of fish, and certain plants containing potent alkaloids.

(2) *Animal parasites*.—Common types of animal foods showing parasitic infection are those containing *Trichinae* or tape worms; as a rule these are due to antemortem infection of the animal. Plant foods, likewise, may bear the eggs or larvae of animal parasites, which later may develop in the body.

(3) *Plant parasites*.—Most foods contain bacteria, and in some cases these may be pathogenic for man. Harmful bacteria come more commonly from animal than vegetable foods, raw milk being especially liable to this form of infection. Tubercu-

1. Author's Note: No originality is claimed for the materials presented in this article, but full acknowledgement is made to Dr. Milton J. Rosenau, who has kindly given me access to advance proofs of certain of his publications, and this contribution is essentially a condensed transcript of Rosenau's most recent investigations on the subject of food poisoning.

Keystone View Company.

That safeguarding the food of the American public is a stupendous job is shown by the fact that New York City's supply of eggs last year numbered about 177,470,520 dozen, the inspection of which is only a small part of the food inspectors' responsibility for the sanitation of the food supply.

losis, diphtheria, septic sore throat, and typhoid fever are important diseases which may be conveyed by some of our commonest foods or by the water we drink. The common cause of food infection is the Gaertner bacillus, or closely allied members of the colon-typhoid group.

(4) *Toxins*.—Poisonous substances may develop in the food due to bacterial action, as in the case of botulism.

(5) *Putrefactive poisons*.—Under this group come the so-called "ptomaines," decomposition products of protein. As Rosenau says: "Ptomaine poisoning is hypothetical and has not been demonstrated. The term is a misnomer and its popularity unfortunate. It is not decomposed but infected food that is apt to cause acute gastro-intestinal attacks."

(6) *Special poisons*.—Ergot in rye is a type of this form.

(7) *Accidental poisons*.—Any poison may be accidentally or intentionally introduced into our food or drink.

(8) *Amount of food*.—Excessive consumption of food predisposes to obesity and possibly to certain types of degenerative diseases. Insufficient food, of course, undermines health.

(9) *Composition*.—Injury may come from an unbalanced diet, and the absence of certain essential food accessories may lead to certain deficiency diseases, such as beriberi, scurvy, rickets, and pellagra. A lack of iodine in our food or water may cause goiter. An excess of fat may cause acidosis; an excess of protein, putrefactive changes; and an excess of carbohydrate, fermentation.

(10) *Digestion and metabolism*.—

Keystone View Company.

That the slogan of the inspector is "Safeguard the Public" is evidenced by the condemnation in New York last year of 7,994,297 pounds of fruit as unsafe for food.

Keystone View Company.

Though the bakers begin their day's work at midnight, the food inspector is on hand to insure that the bakers are clean and healthy and that the baking operations are sanitary.

Wholesome foods may be rendered injurious from faulty digestion or metabolic disturbances, caused by too rapid eating, insufficient mastication, or eating when fatigued or overheated.

(11) *Anaphylaxis*.—It is a common experience that some of us have an idiosyncrasy to certain foods, e. g., sea food, strawberries, eggs, tomatoes, milk, oatmeal, etc.

While all the above named forms of injury which may be attributed to food are of importance, our discussion at the present time will be limited to groups 3 and 4, i. e., food infection caused by *B. enteritidis* and its congeners, and food intoxication caused by the toxin of *B. botulinus*.

It has been a common error in the past to base our classification of food poisoning with relation to the food involved; that is, we have had sausage poisoning, cheese poisoning, fish poisoning, ice cream poisoning, etc. Such a classification is manifestly improper from every standpoint, and it is obvious that the more scientific method of classification is one based on the actual cause of the trouble, regardless of the medium through which it is introduced. According to the best known modern classification, the forms of food poisoning we are now considering are due either to food infection or food intoxication. These two groups are well defined, differing in symptoms, causes and manner of production.

Forms of Food Infection

As already stated, this is generally associated with Gaertner's bacillus or one of its congeners. It is this form

which is commonly erroneously called "ptomaine poisoning." Infected meat being the most common source of infection, it is sometimes called "meat poisoning," although milk, cheese, as well as vegetables, may carry the infection. It generally occurs in warm weather, the higher temperature encouraging the multiplication of the bacteria and increasing the opportunity for carriers like flies to spread the infection. Secondary infections rarely occur and human carriers of the infection are very infrequent.

Unfortunately, organoleptic tests will not always serve as a warning of the infection. In fact, as Rosenau says: "In the vast majority of outbreaks of food infection the food affected is not noticeably altered in either appearance, taste or smell. The prevalent idea that poisonous food must be 'tainted' still persists, although long exploded. Bacilli belonging to the Gaertner bacillus group cannot be detected in food or water, any more than typhoid bacilli, dysentery bacilli, or cholera vibrios can be detected with our unaided senses." In some outbreaks there have been noted objectionable qualities in the food, but these are exceptional, not usual.

This form of poisoning occurs most frequently with meat foods. In 112 British outbreaks, 90 were due to flesh food, chiefly brawn, meat pies, pork, ham, and beef. Pork or beef accounted for 68 per cent of British and 61 per cent of Continental outbreaks. Few outbreaks have been attributed to fish and almost none to mutton or lamb. The poisoning most commonly appears in prepared meat

Keystone View Company.

The small, blue stamp of the meat inspector signifies that the meat is fresh and affected by no impurities. Safe handling is insisted upon in the interest of a wholesome food supply.

foods—brawn, meat pies, sausage, chopped meat. Excessive handling of the food, and long standing at warm temperatures increase the danger of the infection and encourage bacterial multiplication.

Principal Sources of Infection

The infection of the meat of food animals may be antemortem or post-mortem. Cattle suffering from puerperal fever, uterine inflammation, septicemia, septic pyemia, or diarrhea are liable to furnish meat containing bacilli of the type under discussion. The importance of Governmental inspection of meat is therefore apparent, and the danger from uninspected meat or emergency slaughter is equally clear. Infection may likewise occur after slaughter in the meat of healthy animals from the butcher's hands or from implements used on contaminated carcasses, or by fecal contamination, or by human carriers. The last named danger is very remote. In Rosenau's laboratory not a single carrier of bacilli of the Gaertner type was found in more than four thousand specimens of human feces from healthy individuals. Infection from fecal bacteria also is most unlikely. Rats and mice, however, are frequently carriers of these bacilli and the chance of infection from such a source is by no means a remote one.

It must be kept in mind that acute gastro-intestinal disturbances are not necessarily due to harmful foods. Physicians have often fallen into this error in making their diagnoses. The

symptoms of such disturbances may be due to indigestion, indiscreet diet, excessive eating when fatigued, or to nervous or emotional exhaustion. Certain organic diseases of the heart or kidneys show similar symptoms, as do certain acute infectious diseases in children. Rosenau has also shown that alleged "ptomaine poisoning" has been mistaken for cerebrospinal fever, malignant tumor, anaphylaxis, and dysentery. That an alleged case of sickness is due to "ptomaine poisoning" must, therefore, be accepted with many reservations, and leading investigators at the present time even doubt its existence, as is evidenced by the following quotations:

"Ptomaine poisoning is a myth—there is no such thing. Our results at Harvard are positive and convincing" (Rosenau). "The term 'ptomaine poisoning' is clearly incorrect and its retention is unfortunate and misleading, as it leads to a faulty conception of the pathology of the condition, and, what is worse, to the neglect of proper methods of investigation and prevention" (Savage). "Ptomaine poisoning" is a refuge from etiologic uncertainty" (Jordan). "Ptomaine poisoning" is a good name to forget" (Chapin). "The term is incorrect and it should certainly not be used in any scientific publication. A ptomaine, according to Selmi's definition, is a basic product of putrefaction. This is the scientific and proper meaning of the term 'ptomaine' and it should not be applied to food poisoning" (Vaughan).

Prevention of Food Infection

Obviously the surest means of prevention is to have our food as fresh and clean as possible. In foods, canned either in the home or the factory, it is essential that clean, fresh products be used, and that the temperature and period of processing shall be sufficient to kill all pathogenic spores. If the food is refrigerated, a temperature at or near the freezing point must be maintained; if pickled, the brine must be strong enough to prevent bacterial growth.

The main safeguard, however, with foods liable to infection, lies in cooking, which must be thorough in order that the proper heat may penetrate the food. This is of the utmost importance and is often overlooked. Bacilli of the Gaertner group are readily killed in a few minutes at 70 degrees C., but too often in cooking food this temperature is reached only in the superficial layers of the food, while the interior may be relatively cool and many degrees below the

thermal death point. For instance, joints of meat require several hours' boiling to secure an internal temperature of 80 degrees C. In one experiment a twelve pound ham was placed in cold water which was then raised to the boiling point, and it was found that when the water boiled the interior of the ham was only 25 degrees C., and even after two hours certain parts of the interior showed only 46 and 55 degrees. The interior of a rapidly roasted sausage was only 28.7 degrees C. Similar results have been found in the baking of meat pies. Sawyer found that typhoid bacilli survived in spaghetti cooked until the surface was well-browned. The importance of thorough cooking, therefore, cannot be over-emphasized; and this cooking should be recent, just before serving.

As already stated, the first step in the prevention of food infection, especially in meats, rests with the inspector who should condemn any meat from animals suffering from septic or pyemic lesions. Likewise, every pains should be taken to disinfect the hands and butchering tools to prevent the carrying of such infection to healthy carcasses. The cleanly handling exercised in the butchering must be continued throughout all the stages in the meat's progress from the slaughter house to the consumer's table, and at all times the meat must be protected against fecal contamination from flies, rats, or mice. Food should be handled as little as possible, and the health of the food handlers is of course of the greatest importance.

Keystone View Company.

Refrigeration is the object of the closest scrutiny in order to keep it constant and low enough for a wide margin of safety. This is especially important in hotels and restaurants and in the commissaries of institutions.

Foods that have been chopped or otherwise prepared are especially prone to infection, and in such cases proper refrigeration is essential, keeping in mind the fact that the Gaertner bacillus may grow and multiply at temperatures as low as 10 degrees C.

Incidence of Food Intoxication

Poisoning from botulism has attracted special attention during the last two years because of several rather serious local outbreaks. The botulinus bacillus is found in a large variety of foods, both animal and vegetable, and the poison is generated before the food is eaten. Originally this form of poisoning was associated with sausage, hence the name from botulus (sausage). The bacillus is a saprophyte, the toxin developing under anaërobic conditions, and the poisoning is peculiar in that the central nervous system is the chief seat of the intoxication, with no fever and only rarely any acute gastro-intestinal disturbance.

Botulism is much more common in Europe than in the United States. With us it is a rare disease, but its high mortality and the distressing symptoms that accompany it have given it an unfortunate news value, and our newspapers have, therefore, given much prominence to the occasional outbreaks of the past two years, and have caused undue alarm among consumers and distrust of certain important groups of food products. According to Rosenau's statis-

tics in twenty-two years 150 people are recorded in the United States as having been made ill by this form of poisoning, with 111 deaths. Distressing as this is, it is quite insignificant when compared with the toll exacted by several of our familiar diseases, whose victims seldom excite any journalistic interest.

Botulism is peculiar to no sex, age, season or social condition. It appears also among domestic animals, forage poisoning in horses, limberneck in poultry, and possibly some forms of paralysis in various domestic animals, being attributable to it. The habitat of the bacillus in nature has not been definitely determined, but it appears to be an intestinal and soil organism associated with animal excrement. For a time it was believed that certain sections of our country were more liable to harbor this bacillus than others, but recent investigations by Dickson and Meyer have shown it to be quite widely distributed in soils throughout the whole United States.

The thermal death point of the spore has been studied by Weiss, who found that the most resistant types require five hours at 100 degrees, forty minutes at 105 degrees, fifteen minutes at 110 degrees, or six minutes at 120 degrees C. Weiss also found that young spores are more resistant than old ones, dry ones than those that are moist, and that acids, alkalis and various other chemicals greatly reduce the spore's resistance to heat. The fact that these ready means exist for destroying the power of the bacillus is the consumer's chief safeguard, and when this is better realized by the producers of food, both in the home and the factory, the danger from botulinus poisoning will be indeed remote.

Danger in the Toxin

It is not the bacillus, but its toxin, that causes the poisoning. This toxin is a soluble, exotoxin, similar in all respects to those produced by the bacilli of tetanus or diphtheria. It is the only one of the true toxins that is poisonous when taken by the mouth. It is secreted only under anaërobic conditions, between 20 and 30 degrees C. The toxin is remarkably virulent, and there is danger in even tasting any suspicious food.

Van Ermengem showed that the toxin was destroyed by heating for thirty minutes at 80 degrees C., and this has been verified many times, demonstrating that such a procedure offered a wide margin of safety. Other investigators have shown that

Keystone View Company.

Milk inspection in New York City involves the certification of nearly eleven million gallons of ice cream annually, which, uninspected, might constitute a universal menace.

special strains were destroyed at even lower temperature acting through still shorter periods. The toxins of most strains are killed at 65 degrees C. in thirty minutes. So it is apparent that cooking offers us a special safeguard.

A true antitoxin may be obtained by injecting increasing amounts into susceptible animals, and this is both protective and curative, even when given twenty-four hours after the ingestion of the poison, but before the appearance of the characteristic symptoms.

Sources of Botulism

At first it was thought that *B. botulinus* would grow only in sausage or other meat products, but animal protein is no longer believed to be essential for its development. In Europe the foods involved have been mainly meats, such as sausage and ham, but in this country it has been found in ripe olives, spinach, string beans, cottage cheese, corn, asparagus, salad and beets. It has also been attributed to turkey, beef, chicken, and fish.

Frequently in cases of botulism suspicion has been directed against the wrong food. The period of incubation is usually from eighteen to thirty-six hours, and, naturally, several meals may have been consumed between the time of eating the toxic food and the appearance of the initial symptoms of nausea and vomiting. Botulism has occurred most frequently, not in fresh foods, but in those that have undergone some treat-

Keystone View Company.

Two million quarts of milk a day are reasonably safeguarded, or sickness, spread through its contamination would be universal. Bad methods of handling on the part of individuals can negate even the most careful public inspection carried out as a matter of routine

ment, such as pickling, smoking, or canning, or which have been prepared in the home, institution, or restaurant and kept some time before consumption, without proper safeguards. Home packed foods have been responsible for a large proportion of the cases thus far reported, and this is not surprising, for the foods so packed are not always perfectly fresh when put up, the temperature of the processing is often insufficient to kill the botulinus spores, and in general the amateur packer lacks the skill and experience of the commercial canner. The above statement is not meant to imply wholesale condemnation of home packed foods, but there is no question that commercially canned foods are far less liable to botulinus contamination.

As in the case of food infection, no certain reliance can be placed upon odor, taste, or appearance to reveal the presence of the botulinus toxin. In a number of cases of this form of poisoning there has been evidence of taint as revealed either by the food's odor or unpleasant taste; but, unfortunately, this is not always true. The safest procedure is to avoid eating abnormally soft, mushy foods, which show gas or other evidence of putrefaction.

Prevention of Botulism

Botulism is prevented chiefly by greater care in the handling and preparation of nitrogenous foods. There is no danger of such poisoning in fresh foods, for in them the anaerobic conditions necessary for the development of the toxin do not exist. As stated before, the danger of botulism appears to be chiefly in home canned foods, which emphasizes the necessity for the adoption of safe methods by home canners, especially the employment of sufficient heat to kill the spores, and the avoidance of all raw materials that is not fresh and clean. The same necessity of course rests with the commercial canner, but generally because of his greater experience and more scientific equipment, the conditions favorable to the development of the bacillus are less liable to occur in the factory than in the home.

The botulinus toxin is destroyed in ten minutes at 80 degrees C., and cooking, therefore, is a safeguard, but this must meet the above-named conditions of temperature and time. Home canned, and also commercially canned, foods, except milk and acid foods, should be cooked again before serving. The toxin may reform in cooked food that has been allowed to

stand twenty-four hours at room temperature, so proper refrigeration of such food is essential in preventing the possibility of botulism.

Attention has already been directed to the fact that organoleptic tests are by no means an infallible guide in detecting food liable to produce botulism. It is essential, therefore, that consumers and producers should alike be educated as to the importance

of the proper precautions to be taken in the preparation and cooking of food. Proper heat and proper cold are sure preventives, but there must be no uncertainty as to the maintenance of these proper temperatures for a sufficient time either to prevent the development of the toxin, or to effect its destruction. Wider knowledge and better practices in food sanitation are the best safeguards.

Combats Venereal Disease

BY C.-E. A. WINSLOW, M.D., GENERAL MEDICAL DIRECTOR, THE LEAGUE OF RED CROSS SOCIETIES, GENEVA, SWITZERLAND

THE second of the regional conferences on venereal disease, arranged under the auspices of the League of Red Cross Societies—the first having been held at Washington last fall—took place at Copenhagen, May 20-25. It was held on the invitation of the Danish Red Cross and included the seven North European countries, Denmark, England, Finland, Germany, Holland, Norway, and Sweden, represented by such eminent men as Rasch, Ehlers and Madsen of Copenhagen, Harrison and Kay Menzies of London, Galewsky of Dresden, Gron of Christiania, and Marcus and Ribbing of Stockholm.

The nations participating in this conference are among the most advanced in the world in their venereal disease programs. From the social side, England and Holland have had nothing like official toleration of prostitution for a hundred years. Norway abolished so-called "regulation" of prostitutes in 1888, Denmark in 1906, and Sweden in 1918; while Germany and Finland are planning similar action in the immediate future. Thus, all of these countries will shortly be on a "abolitionist" basis; and the Conference was unanimously of the opinion that the practice of regulation is medically useless and may prove positively harmful as tending to give official sanction to a vicious traffic.

Progress in Treatment

It is in connection with the medical control and treatment of venereal disease that the countries of northern Europe have made most notable progress. There are sharp lines of differentiation, however, between their policies, differences due chiefly to national psychology rather than to any divergence in principle. Thus the notification of venereal diseases (by number) is required by law in Denmark, Norway, and Sweden, but not

in England, Germany, and Holland. Denmark and Sweden have laws—like those of certain of our American States, but much better enforced—which require compulsory treatment for all known cases of venereal disease; England, Germany, and Norway have no compulsory treatment, but recognize the duty of the state to provide free treatment for all who will avail themselves of it; Holland does not agree to the principle of universal free treatment, although ample facilities are furnished to those who cannot afford the cost. The Conference was absolutely in accord in holding the provision of free dispensary treatment for all who would not otherwise obtain it to be one of the most essential factors in the campaign against venereal disease.

The extent to which dispensary treatment is actually secured may, of course, be as great under a voluntary as under a compulsory treatment plan. In England a very extensive system of free voluntary treatment has been provided which included more than one hundred thousand new patients in 1920. The clinics in the large cities are now kept open all day long. In Stockholm, with a compulsory law, nearly twelve thousand patients received treatment in 1912, about thirty new patients per one thousand population. There were eleven visits per patient per year in Stockholm, and nearly fifteen visits per patient per year in England and Wales, both remarkably good figures.

Denmark and Sweden Lead

Denmark and Sweden have on the whole the most complete medical programs for the treatment of venereal disease which are to be found in Europe. Denmark recognized the principle of universal free treatment as early as 1790, and Sweden introduced the system of anonymous notification in 1817. In both countries all cases

must be reported by number and must continue under treatment until cured, failure to report to the physician in charge at the specified time—unless the original physician is notified of transfer to another physician—being followed by a report to the health authorities of the name of the delinquent. Denmark has a particularly admirable card catalogue of all reported cases based on date of birth, initial of family name—which must be included on the report—sex, date of original diagnosis, and name of the physician or institution giving the first treatment. Reports of the Wassermann test are also recorded on these cards, and since over forty-three thousand Wassermann tests were made at the Royal Institute of Serology in 1920, the results are of sufficient extent to prove of both scientific and administrative value. Medical facilities are free for all venereal cases, and are generously provided. Copenhagen has four hundred hospital beds for such cases, or one bed per two thousand population, about 3,500 cases per year receiving treatment. There are no quacks in Copenhagen; and it is believed that nine-tenths of all cases are treated by qualified specialists. Severe penalties are provided in both Denmark and Sweden for the conscious exposure of another person to venereal infection. A particularly interesting phase of the Swedish system is the search for sources of infection. Each patient consulting a physician is requested, but not compelled, to give the name and address of the person by whom he or she was presumably infected and when this can be done the infecting person is sought out, examined and brought under treatment.

From the standpoint of popular education, which was considered by the Conference as a fundamental essential in combating venereal disease, the experience of England and Germany is most extensive. Local health authorities in England are required by the Ministry of Health to provide for such education, which is largely carried out in cooperation with the National Council for Combating Venereal Diseases, a voluntary organization receiving large grants of money from the Government. This Council spent about \$25,000 on newspaper advertising alone in the year April, 1920, to March, 1921, and received nearly thirty-five thousand letters of inquiry as a direct result. The German Society for Combating Venereal Diseases has also carried on an admirable plan of propaganda by the use of lectures, films, and leaflets.

So far as specific training in Sex hygiene in elementary schools is concerned, opinion in England is adverse, but in Sweden, where education does not cease at fourteen, as has generally been the case in England, but continues to the age of sixteen, a Royal Commission appointed for the purpose has recently (March, 1921) presented a report recommending an extensive and detailed system of sex education. It suggests a short compulsory course for all pupils at about the age of fifteen and a second more advanced course for the students who continue in secondary schools till eighteen or nineteen. The training of all teachers in sex hygiene was insisted upon by all the members of the Conference, whether formal instruction of pupils be a part of the school curriculum or not.

The Copenhagen Conference marked a definite step forward on the road toward a constructive world program for combating venereal disease; and it is of interest to note that the statistics of reported cases for Denmark and Sweden and the statistics of treated cases for England all indicate a decrease of venereal disease since 1919, whether as a result of the passing of war conditions or as a result of the public health campaign, it is yet too soon to say.

Child Hygiene Extended

It has been announced by the New York City Department of Health that through the combined efforts of the Bureau of Child Hygiene, the Department of Education, the Red Cross, and the Civic Club, an examination of the pre-school children who are to be registered in school next September was begun on May 31 in every school in Manhattan. The work will continue until the end of the present school year and it is expected that about 1,000 children will be examined. The physical defects will be corrected so far as possible before the children enter school. A study will be made of the effect of the removal of these defects upon the mental status of the children, the latter examinations being conducted by the Department of Education.

Industrial Medicine for Germany

The Prussian Government has appointed a chief industrial physician to supervise matters of industrial hygiene, the appointee being Dr. Ludwig Teleky of Vienna, a widely known expert on the subject.

Dr. Livingston Farrand Goes to Cornell

The achievements of Dr. Livingston Farrand are known to thousands, eminently fitting him to fill his new capacity as president of Cornell University. A member of the 1888 class of Princeton, he took his degree as Doctor of Medicine from the College of Physicians and Surgeons at Columbia in 1891, after which he had a year of study in Cambridge and one in Berlin, when he returned to teach at Columbia, where he was in the Department of Psychology until 1903, and thereafter held the Chair of Anthropology until 1914. During this period he accompanied two expeditions of the American Museum of Natural History, under Dr. Boaz, to study the

Indians on the coast of Washington and British Columbia.

His first big piece of executive organization he accomplished as executive secretary of the National Association for the Prevention of Tuberculosis and was a marked example of his gift for making opposing factions pull together. As president of the University of Colorado in 1914 he reorganized the university's medical school, another demonstration of marked executive ability.

His executive work with the American Red Cross is familiar to everyone and exemplifies his faculty for leadership. A physician by training, his medical knowledge has been used only in research and as a basis for medical executive work. His experience in organization, and his work in France, and his knowledge of diplomacy will serve him excellently in his new post.

Light Much Neglected in Efficiency Promotion

Psychology as Well as Physiology Enters into Successful Lighting

By S. E. DOANE, CHIEF ENGINEER, NATIONAL LAMP WORKS OF GENERAL ELECTRIC COMPANY, CLEVELAND, OHIO

BECAUSE the eye is so perfectly designed that it is automatic in its action, and because it is so carefully built that it withstands abuse day after day without complaint, we find, as we might expect, that the conditions under which it is required to work receive relatively little attention.

It is true that modern factory and office buildings are planned with a view to utilizing daylight to good advantage, but the mechanic who rents a barn as the first step toward a garage or service station of his own contents himself with windows as he finds them. It is true that lighting is now receiving attention in the public schools, but the child will do studying at home under artificial lighting of a very indifferent quality.

Wide Range of Power

The variations in lighting range from several thousand "foot-candles" outdoors on a sunny day to the fraction of a "foot-candle" which may obtain in the central portion of an industrial interior on a cloudy day. Certain it is that if the eye had to be adjusted consciously as we would adjust a camera for these wide variations, we would give careful consideration to providing illumination of a character which would enable the eye to devote more of its energies to visualizing and less to see-sawing back and forth in constantly varying adjustment.

Washington used candles. Lincoln studied by the flickering flames of a fireplace. Most of us have used the kerosene lamp. Electric lighting is relatively new. It was in 1879 that the first incandescent lamps were placed on the market.

For the next score of years, manufacturers devoted themselves almost entirely to improving the lamp itself.

Then the idea took root that lamps were merely a means to illumination.

The illuminating engineers, who were born to meet the need, dug into the fundamentals of lighting and laid a firm foundation upon which lighting progress could be built.

This foundation was being laid slowly, but carefully, when the rush of the war activity forced an unexpectedly strenuous trial of the the-

If some of the attention the eye has commanded as a fine instrument of accommodation were transferred to the consideration of its limitations, many obscure causes of ill health, fatigue, and unrest would be eliminated.

In illuminating the work place the hygiene of the eye needs to be considered first, the adaptation of the worker second, and increased production last; but all these interests are equally served by scientific lighting.

ories of these engineers and found them true. Thus was begun a new era in lighting.

It is because artificial light has been, in the past, regarded too lightly in the scheme of industrial efficiency that we have today what is so generally characterized as a new era in lighting in industrial and electrical circles. The past few years have witnessed no phenomenal inventions or developments of light sources. Improvements have been made, it is true, but the lamps are only more perfect editions of the copy of five years ago.

The age-old lighting idea has been changed, due in part to the impetus given it by lighting men trying to establish their theories, but due, in the main, to the outstanding records that proper lighting has made when

on its merits alone. Therefore artificial lighting has been more or less of a supplementary matter, simply an available service to be called on to help out daylight in the early morning or late evening hours. But when the war requirement called on certain industries for twenty-four hours production, it was necessary for artificial light, not to supplement but actually substitute for daylight. Illuminating engineering then became a reality.

Safety a By-Product

Our post-war invoice of the standing of lighting showed us that the general attitude of the industrial men was changing from one extreme to the other; where before lighting cost had been a burdensome operating expense to be curtailed wherever possible, it now became a factor which paid handsome dividends in utility, production, and profits.

It is common knowledge that for the eyes to function, light must be supplied in some measure; but just how much is needed for best vision is a matter of speculation. It is also a matter of common experience that when the daylight begins to fade or on dark cloudy days we have to make more of an effort to see details which were clearly visible when there was plenty of light. It follows then that the amount of light supplied has a great deal to do with our ability to see quickly and accurately. When factory tests indicated that increased production was the direct consequence of more light, it was first thought that light had merely a stimulating effect which caused the workmen to move faster and thus to accomplish more in a given time. But as the results were further analyzed it was found that spoilage decreased and the accident rate diminished. The obvious conclusion was, then, that the light was allowing the workman to proceed with his work *unhindered* at his normal pace. In other words, it does not add another brick to the hod-carrier's load in his effort to get more done but it merely serves to remove an obstacle which has hindered his normal progress.

Let us consider the gain to the country of a general improvement of lighting conditions as indicated by sta-

Fig. 1.—Here the foot-candle meter is used to measure the illumination on the work.

Fig. 2.—As a strictly local lighting system, this might be described as good, yet the appearance of the room is dark and depressing. Reflections of the lamp filaments in the working surfaces are likewise a source of considerable annoyance to the workmen, whose comfort is always an important factor and affects their general attitude toward the shop

tistics at present available. As far as taking the brakes off production is concerned, all tests have shown an increase in production during lighting hours, some as high as 35 per cent. As regards spoilage, it is estimated that of the \$350,000,000 wasted annually in the United States thirty million dollars is directly chargeable to poor illumination.

Recent statistics from insurance companies attribute 15 per cent of all industrial accidents directly to inadequate or improper illumination. Reduced to a dollar-and-cents basis, the equivalent loss to the industries by accidents chargeable to poor lighting amounts to three hundred thousand dollars. This is a sum in excess of our yearly industrial lighting bill, and hence we can see that one result alone of the misuse and inadequate use of our lighting facilities in industry costs more than the light itself!

A number of states have taken cognizance of lighting in connection with the safety movement and have adopted codes designed to regulate industrial lighting.

From this same standpoint, too, the industrial physician is concerned. If an effort is being made to reduce the accident rate or if the contributing causes are being sought, it would be well to inspect the lighting. As we have already stated, the eye is apparently capable of withstanding a great deal of abuse and for this reason bad conditions are sometimes not discovered until an accident occurs; or are not readily apparent on slight inspection, but manifest themselves after a time.

One lighting expert found on such investigation that in one machine shop there was a drill press known to have a "hoodoo." Anyone who worked at

this drill press was certain to have an accident before very long. Men were even known to quit the plant rather than attempt to work on this machine.

The lighting expert discovered that these accidents had been caused by a reflection due to the peculiar way in which this drill press happened to be lighted. The operator was continuously handicapped by this little reflection flashing back and forth in his eyes. It was slight, to be sure, but on account of the regularity with which it occurred, the operator became almost hypnotized.

At least, it caused the accidents, for

as soon as the lighting had been changed, accidents ceased.

Cause May Be Obscure

It is not always easy to discover an obscure cause like this; however, if any machine seems to be responsible for a large number of accidents, the one thing which should be examined first, is the lighting.

Another instance of somewhat similar nature was recently encountered in a machine shop of a large industrial concern in northern Ohio. It had been observed for some time that one row of four lathes was being shunned by the machinists whenever possible, the men oftentimes carrying their work to lathes located at the far end of the shop when occasion compelled the use of a lathe. The continued idleness of these four lathes finally caused the foreman to investigate.

The workmen could give no valid reason for not using these lathes, simply saying that they "did not like to work on them." After thoroughly inspecting the working parts of the machines and finding nothing wrong mechanically, the foreman casually glanced out of the nearest window and in so doing, discovered the cause of the trouble. In front of each of the four lathes was a large window which allowed a flood of daylight to shine directly into the eyes of the operator. The glare resulting from this condition had produced an unpleasant physical and mental reaction

Fig. 3.—The same room shown in Figure 2, after modern lighting was installed. The "forest of belting" does not prevent an adequate supply of properly diffused light from reaching the work from a general overhead system. The contrasted lighting conditions reflect the truth of statements of more contented workmen, increased production and decreased accidents under good lighting.

on the men, and despite the fact that the machines were in perfect mechanical condition, the men "did not like to work at them."

The situation analyzed, an effective daytime remedy which overcame all previous prejudice consisted simply of reversing the position of the lathes so that the operators worked with their backs to the window.

More than Light in Lighting

These actual happenings indicate that there is something more to be considered in lighting than the amount of light. In speaking of the benefits of proper illumination, it may have seemed that the amount of light was the thing of first importance in good lighting. As a matter of fact, the two examples just mentioned were not occasioned by lack of light but by defective or improper lighting. Glare and reflected glare, or, in popular words, "light which shines in the eyes" present not only a negative condition for vision but a positive menace as well which counteracts the usual effect of enough light. In milder forms, glare may not actually cause visual defects but in all prob-

Fig. 4.—*Showing the effect of increase of intensity of light on acuity, acuity plotted against foot-candles of light to the surface of test objects.

ability it will produce a mental dissatisfaction which is difficult to account for and for which the true cause may be least suspected.

There are then three important factors which go to make up good illumination, namely: (1) Amount of light, (2) quality of light, and (3) direction of light.

I have spoken in general terms concerning amount of light but unfor-

Fig. 5.—*Showing the effect of increase of intensity of light on speed of discrimination for eyes with normal refraction.

Fig. 8.—The glaring local light shown in this picture is a menace to safety and vision. It is one of the evils which state lighting codes are aiming to destroy.

tunately that is a term of which the average man has little conception. Speak of "amount of light" in a room to the ordinary layman and his

Fig. 6.—*Showing the effect of increase of intensity of light on speed of discrimination for eyes with normal refraction and same eyes made slightly astigmatic.

thoughts and eyes instinctively turn to the lamps to see if they are bright and glaring; if so, naturally there is plenty of light. But as a matter of fact, looking at the lighted lamp to

Fig. 7.—*Showing the effect of increase of intensity of light on speed of adjustment of eye for clear seeing at different distances for eyes with normal refraction and same eyes made slightly astigmatic.

determine the amount of light in a room is like putting your hand on the stove to determine therefrom the temperature of the room. Carrying the analogy further, we now measure illumination in "foot-candles" with a foot-candle meter in the same way that we measure the temperature in a room in degrees with a thermometer (Fig. 1). When we say we have five, ten, or twenty foot-candles of illumination, we mean that we have a certain quantity of light on the working plane which is quite independent of the size of lamps used to generate or "manufacture" this necessary quantity of light. The Figures 4 to 7 show the relation of "amount of illumination" to visual results.

Must Diffuse the Light

We have the evils of glare and reflected glare which are ever present in some degree where sources are within the field of vision. All lamps should be shielded by diffusing glassware or other diffusing medium so that the brightness of the unit either in itself or in contrast to its background will not prove annoying. Color quality, direction of light, uniformity of illumination, and other considerations no less important than those which have been briefly touched upon, are all factors which must be given attention in a properly designed lighting system.

I wish to take this opportunity to direct the reader's attention to the work of the Illuminating Engineering

*Ferree and Rand: Transactions Illuminating Engineering Society, 1920.

Society, which is a scientific organization free from commercial influences, devoted to the accumulation and dissemination of information on lighting. This Society has been very active in providing the foundation of facts upon which all the state lighting codes have been built. It has co-

operated with many other national societies and federal bodies in matters pertaining to lighting. It has done much to further improvements in school lighting believing that the protection of our children's eyesight is a responsibility which cannot be shirked. The *Transactions of the Illuminating*

Engineering Society are full of facts on these and many other phases of lighting which should receive the attention of those responsible for the health of the individual, the group, or the public. Economy as well as the interests of good health calls for the universal consideration of these matters.

Research of American Institute of Baking

Laboratory Service to the Baker Means Better Nutrition at Less Cost

BY H. E. BARNARD, PH.D., DIRECTOR, MINNEAPOLIS, MINN.

IN MORE ways than one the baker is an important servant of mankind. His product is the most important food of the white race. It is consumed in greater quantity and provides nutriment more cheaply than any other staple. It is on every table at every meal and yet, until the stress of war drove deep into the hearts of our people the fact that wheat was a munition as essential as shells or explosives, its real value was little appreciated. We ate bread as a matter of course, never thinking of its production as a basic and vital industry. The old couplet referring to the butcher, the baker, the candlestick maker, still serves to link essential trades together. And yet the butcher, who wastefully dressed an occasional beeve, has given way to the packer who handles the live stock from pastures a thousand miles apart so scientifically that waste is eliminated; the candlestick maker put away his moulds when kerosene filled the family lamp; the baker is the only figure in the trio who survives. But he is ambitious, too. His little, dark, one oven shop with its wooden troughs and handmade doughs is being converted into sunlit, sanitary laboratories where flour is handled with all the deference its amazing values as a chemical substance demands and with all the scientific skill necessary to its manufacture into perfect bread.

Baker Has His Vision

During the war the baking industry operated under license from the United States Food Administration. It used the formulas set for it. It made the loaves it was permitted to make. It went through travails which threatened to crush it and yet, when the regulations were abolished, it came out a better informed, broader visioned, more compact industry than ever before in all history. And the

baker had a vision in his days of trouble. He saw as never before the real purpose of his shop and he has set himself to realize it. He is determined to take baking, the last of the primitive household duties, out of the home and put it in the factory, just as the weaving of cloth, the making of shoes, the washing of clothes have been lifted from the shoulders of modern womankind and transferred to the soulless machine.

But the baker knows that he cannot convince all bread eaters that his product equals and even surpasses the quality of "mother's" bread by billboard statements. Bread flavor is too subtle, and yet too fraught with childhood memories of the open oven door to be fixed by the psychological appeal of printed words and alluring pictures. It must be in the loaf if the baker ever succeeds in his determination to make home baking a lost art.

The American Association of the

Baking Industry is the group of men who worked so successfully with Herbert Hoover in the conservation of flour for shipment over seas. These bakers then learned the need of replacing the "rule of thumb" practices of pioneer industry by production methods based on definite knowledge of the chemical and biological processes that enter into the baking of the loaf. And so in 1919 they put their ambition for a greater bread industry into the form of a permanent endowment fund and founded the American Institute of Baking.

The Institute, located at Minneapolis, furnishes the opportunity for the study of the baker's problems and troubles in well equipped research and baking laboratories and adapts the results of scientific investigation to practical use in the shop. While its fundamental purpose is to place the baking industry on a scientific basis, the Institute furnishes the in-

Laboratory methods are as precise for the baking industry, and equipment as minutely adapted to its purposes as in other fields of research.

All materials are tested for purity and for exact fitness for specific use.

formation necessary to improved bakery practice through its Technical and Service Department and through a library service which reviews the literature of the baking industry and adapts it for publication either in special bulletins or through the trade papers. The scope of the work is well set out in an early prospectus which is here quoted in part as follows:

The Institute encourages the discovery of and investigates and makes known to its members the nature and merits of new inventions and improvements in processes and materials. It cooperates in the development of standard methods of analyses and tests and in establishing standard specifications for baking materials and bakery products.

It obtains data on the character of the wheats from the different producing sections of the country, as soon as threshing begins, and advises the baking industry how the different flours from these wheats can be blended and used in making the ideal loaf.

It studies the different types of bread and is developing a standard system of scoring each type and in general recommends the most satisfactory methods of handling raw materials and mechanical devices in producing these breads.

The Institute encourages and improves the education of persons engaged or who intend to engage in the production of bakery products, its laboratories functioning, in some instances, as a sort of post-graduate school.

The Institute cooperates with other organizations in the solution of problems of general interest, such as bakery sanitation, the health of workers, the nutritive value of bread, the adoption of suitable dietaries by workers in the several fields of industry.

The work of the Research Department of the American Institute of Baking is the study and investigation of those chemical, physical and biological problems which underlie the art and science of bread making and the interpretation and application of the results of such studies to the needs and advancement of the baking industry. These problems are numerous and complex and the selection of any one of them will lead to many unknown investigations the nature and value of which cannot be predicted. Some of these subsidiary problems may be of practical value and others may have for the present but the interest of a problem in pure science. Some of the major projects which are being studied are as follows:

(1) Moisture retention in bread, and the prevention of staleness.

(2) The study of sweetening agents, malt syrups and other cheap sugars.

(3) Shortening agents and their effect on fermentation.

(4) The activation of fermentation, so that the time consumed in the usual processes may be shortened.

(5) The development of practical control tests for bakeries lacking laboratory facilities.

(6) The study of standard and uniform methods of analysis for flours and other baking materials.

These are but a few of the problems which seem to command immediate interest. Others that may be studied are the question of flavor, yeasts and yeast foods, the relation between physiochemical properties of flours and their baking qualities, and the investigation of new and improved methods of analysis of baking materials.

Bulletins Are Issued.

In the year since the Institute began its work a number of bulletins have been published by its Research Department. One bulletin deals with the control of rope, a bacterial infection which causes the baker much loss and trouble in the summer months. Another is a compilation of all the laws and regulations which the Federal Government and the states have set up to regulate the composition of the raw materials used by the baker—the flour, sugars, condensed milks, and shortenings which make up his formulas. A third bulletin details the methods of analysis used in examining these materials and points out the need for better methods. Indeed, in some ways the science of baking

The American Institute of Baking has for the first time made the necessary correlation between the physicochemical properties of the constituents of breads and the finished products. All frauds and fraudulent materials are exposed by unbiased scientific method.

is outstripping the chemists in the allied industries.

The primary function of the Technical and Service Department is the solution of problems which do not require the extended investigations and large amount of new work which characterize the activities of the Research Department.

Technical Service Helpful

While the technical facilities of the Institute are used largely to supplement and assist in problems of pure research, a service is being built up which offers the baker a rapid solution of momentary difficulties of any nature and supplies information on technical or chemical questions.

With these purposes in view, this department has been equipped along three lines so that an excellent chemical laboratory is available for the purely chemical work; a baking laboratory which permits making bread by almost any method of procedure, and an engineering office is maintained where the problems dealing with building construction, power, heating, ventilation, wrapping, etc., are given attention.

An incidental function of this department is the examination of all specific products and materials offered the baking trade, especially where unusual qualities are claimed. A watchful eye is kept for fraud, and such frauds are exposed without bias. For the purpose of showing the character of the services which are rendered by the Technical and Service Department, a number of pertinent problems are listed below:

All data collected, and all observations made are brought together and made available everywhere through an efficiently administered information service.

Consultation, advice and critical examination on chemical, technical or engineering subjects suggested or presented by members of the Association.

Laboratory examination of the stocks of flour and a standardization of specifications for the different characteristic grades produced from each wheat crop.

Baking characteristics of each of the grades established above, and bulletins giving recommendations for the use of each class of flour, including advice in anticipation of questions of blending which may arise where the supply consists of two or more types of flour.

Location of abnormal stocks of flour in the country and, as far as it is possible to give it, advice as to how to use any unusual quality so found or to counteract defects discovered.

Examination of all shortening materials on the market.

Examination of yeast foods and comparative bakes with the same, using various types of flour for each food.

Examination of milk products, the publication of chemical data and the results of comparative baking tests.

Study of the different types of bread, classification of this bread by type with the development of a score sheet for each type; bulletins giving types of bread demanded in different parts of the country and a score system for each. The method of producing a perfect loaf of each type, with recommendations as to the raw material, method of production and the use of mechanical devices.

Suggestions for making all tests required in the control of a bakery.

Bulletins on fuels, bakery lighting and ventilation, temperature and humidity control, etc.

Investigation of commercial lubricants, and bulletins giving specifications of proper lubricants for different standard bakery machinery bearings.

Bibliography of Breads

The literature of bread, yeasts, ferments, and indeed of the entire cereal and baking industry, is meager and not readily available. The Institute, realizing the value of having at hand as a part of its working equipment complete data on the subjects with

The scientific study of an industry evolves better objectives, better machines, better control, and, in the case of the baker, a better loaf

which it is concerned, is establishing a library to be known as the Library of the American Institute of Baking. The library will be used as a repository for all the results obtained in the laboratories and will supply the data and facilities required by the Information Service in handling the following projects:

(1) Maintenance of a complete record of available data on bread, so arranged that desired information can be immediately located.

(2) Answers to inquiries, provided the information is available in the literature or obtainable in the laboratories.

(3) The publication of abstracts of technical information in the baking field.

(4) Copy or translation of technical articles in foreign languages when requested by members.

(5) Analysis and record of results obtained through research.

(6) Service in editing material for publication or for circulation to the members.

(7) Preparation of bibliographies covering the subjects under investigation, or of special interest to the members.

It is obviously impossible to cover the broad field of the science of bread making in a single laboratory. Fortunately, the National Research Council is coordinating the research activities of the scientific world. Through the Council an Advisory Board has been organized for the purpose of correlating the work of their own laboratories with that of the Institute. The members who are on this board are leaders in their several fields, as the list will show:

Dr. Samuel C. Prescott, professor of industrial microbiology, Massachusetts Institute of Technology, Cambridge Mass.

Dr. Wilder D. Bancroft, professor of physical chemistry, Cornell University, Ithaca, N. Y.; chairman, Division of Chemistry and Chemical Technology, National Research Council.

Dr. C. E. Mendenhall, professor of physics, University of Wisconsin, Madison, Wis.; chairman, Division of Physical Science, National Research Council.

Dr. E. V. McCollum, professor of biological chemistry, School of Public Health and Hygiene, Johns Hopkins University, Baltimore, Md.

Dr. L. B. Mendel, professor of physiological chemistry, Yale University, New Haven, Conn.; member of Inter-Allied Scientific Food Commission.

Dr. John R. Murlin, director of Department of Vital Economics, University of Rochester, Rochester, N. Y.; chairman, Committee on Food and Nutrition, National Research Council; late director of the Division of Food

and Nutrition, Medical Department of the United States Army.

Dr. Alonzo E. Taylor, professor of biological chemistry, University of Pennsylvania, Philadelphia, Pa.; scientific adviser to United States Food Administrator.

Dr. G. H. A. Clowes, research chemist, Eli Lilly & Co., Indianapolis, Ind.

Dr. L. J. Henderson, professor of biological chemistry, Harvard University, Cambridge, Mass.

This Board is already functioning with our staff and several problems of scientific and practical interest are in the hands of the members of the Board. No greater assurance of the value of the Institute can be given than the knowledge that such men as Henderson, Bancroft, Prescott, Mendenhall and Clowes are, with us, hunting for the answers to our problems in preventing staling, stimulating enzymic action, controlling fermentation, strengthening glutens and perfecting methods for determining acidity. No brighter promise of a better nourished people can be given than the fact that the leaders in the study of nutrition, Mendel, McCollum, Murlin and Taylor, are bringing to our aid all the help that their researches with proteins, fats, the growth-promoting substances, the antiscorbutic principles, and the economies of an assured food supply can give them.

A few years ago all bread not made at home came from the retail shop. Today the business of the retail baker is chiefly the making of cakes and pastries and between 40 and 50 per cent of all bread consumed is made in the great bakeries and reaches the consumer through the grocer. This grocer may be around the corner from

the bakery or he may have his shop in some little prairie town three hundred miles away. Bread is no longer a perishable article, fit for eating only when fresh from the oven. Modern methods of baking, coupled with the use of a sanitary and moisture holding bread wrapper has so lengthened the life of the loaf that it reaches the consumer's table in perfect condition three days after baking and hundreds of miles away.

Better than Home Made.

But it is not enough that 50 per cent of the bread supply is baked in the shop. The baker has confidence in his ability to make a better loaf of bread than the housewife. He has a wide choice of materials. He can buy better flour than the housewife, whose only knowledge of flour character is that indicated by a brand. He has better utensils and machines for mixing and fermenting his doughs. His rooms are kept under exact temperature and humidity control. His ovens are uniform in temperature and bake more evenly than the simple oven of the kitchen stove. His product is uniform in character. It is a better loaf than his only competitor's, the housewife who still observes baking day.

And baker's bread is not only being produced in larger volume every month, but it is by its cheapness and excellence steadily increasing the carbohydrate intake of the people, and this is greatly to be desired. Dr. Alonzo E. Taylor has frequently called attention to the necessity of revising the dietary in the interest of

The ovens are uniform in temperature, the product more uniform under scientifically controlled conditions.

better nutrition at less cost. He points out that the American consumption of bread, as compared with that of the English, French, and Italian, is decidedly lower and he says that our bread intake can and should be increased from its present 35 to 40 per cent of our food consumption to 60 per cent.

Science Improves Product

The American Institute of Baking is supplying the baking industry with the scientific facts which make this high set ideal possible. If bread is better in taste, higher in nutritive value, and cheaper in cost it will be eaten in larger quantities. And it is the purpose of the Institute to teach the baker how to make better tasting, more nutritious, and cheaper bread. It is operating today that it may serve the baker and through him the consumer. It has brought the scien-

tist from his laboratory at the university and placed him in the practical laboratory of the baker. It is teaching the baker that the chemistry of flour, sugars, and shortenings, the biology of yeasts and ferments, the physics of glutens, humidities, and temperatures are none the less true science when applied in the manufacture of bread instead of in the solution of some abstract problem. Indeed, it is arousing in the scientist the conviction that no field of study is as full of fruitful problems as that of the bakeshop, and no opportunity for service so great as that offered in the production of a better loaf of bread through which to nourish mankind. It replaces old methods of prolonged and uncontrolled experimentation with the scientific precision which assures a uniformly high standard of product, a constant nutritional value, and vast economic gain.

Helps Rural Home Makers

By MARTHA VAN RENSSELAER, DEPARTMENT OF HOME ECONOMICS, CORNELL UNIVERSITY, ITHACA, N. Y.

TO preach thrift is one thing, but to make it attractive and to "put it across" is another, for it deals with adults whose habits are fixed, with individual tastes and family prejudices which need to be countered, and with the universal tendency to lay the blame for personal difficulties upon some remote or external cause. Thrift may be defined as effectual behavior in the face of economic pressure. It implies the use to the utmost of all the means at hand, and that without

sacrifice of comfort, of health, or of peace of mind. It involves a clear vision of the problem and resolute and consistent measures to meet it.

How, then, can one make effective a campaign to make thrift appear attractive and possible of achievement? Certainly not as a charitable enterprise, nor even as a business adventure, though it is both humanitarian and economically sound.

The only way to make effectual a program of this kind is to demonstrate objectively its immediate ap-

plication to the difficulties of a given locality. It must in the first instance take on a community rather than an individual aspect, depending for its appeal upon the concrete evidence offered of its application to the individual problem.

The "Victory Special" is a demonstration train that was sent out primarily to throw light upon the various means of shaping the family living in rural communities of the state of New York to the high prices incident to post-war conditions. It was under the auspices of the Department of Home Economics of the New York State College of Agriculture, and experts from Cornell University conducted demonstrations and gave lectures on how to simplify housekeeping, how to keep well, how to buy the best values in food, how to conserve the surplus, how best to serve and preserve foods, how to make over old clothes, in short, how to practice economy without needless worry and sacrifice. The exhibits included home made and commercial labor-saving devices, home made garments demonstrating possibilities in the way of remodeling and renovating of clothes, convenient working arrangements for the kitchen, artistic values in home decorations, and many other things of interest to the homemaker.

The success of the enterprise everywhere has led to the continuation of the method in Home Bureau work designed to alleviate the difficulties of rural homemakers, and to emphasize the community relationships growing out of the mutual needs of isolated districts. It is significant that everywhere individual work has been followed by community organization, for

The work of the Department of Home Economics of the State College of Agriculture is carried to the isolated rural home maker by means of expert advice, demonstrations in the use of labor saving devices, and instruction in economies that do not cost in comfort or health on the part of those who practise them.

The "Victory Special" is composed of two cars, one for exhibits and the other for demonstrations. Visitors are shown how to make fireless cookers and iceless refrigerators, as well as plans for convenient kitchens, airy bedrooms, and attractive living rooms. Experts in home economics give advice on special problems.

The virtue of economy has a better appeal when attractive dishes have not because of economy sacrificed their flavor of delicacy. No small part of the housewife's difficulties being concerned with how to feed the family well and practice thrift at the same time.

The train is open all day. Two specialists from Cornell University give lectures on the use of foods and newer methods in their preparation and preservation. All questions on individual problems are answered.

nowhere does the individual problem remain isolated. The efficient home has its influence in the community. It is emulated by the less effectual groups. It demands better service of its schools, of its country stores, and it learns to apply to its public service the same criteria of effectiveness that have made for the intelligent administration of the home.

Figures are presented to prove the value of the measures which have grown out of the extension service of the Department of Home Economics. Home bureaus have been organized in half the counties of New York state. Hot lunches have been served in more than two hundred rural schools. Home-making courses have been introduced, and the same systematic care given in rural schools to malnourished children that has heretofore been employed exclusively in urban communities.

Another advantage has resulted in the creation of a larger community spirit by means of recreational activities. Library units have been established, clean-up days instituted, community centers created, sings, plays, and pageants arranged, so that the people in the rural communities reached need be isolated no longer if they seize the opportunities offered for extending their common interests.

However much of immediate improvement may be attributed to the thrift campaign *per se*, the greatest social gain is in the attitude of the community in facing their own problems, and in the achievement of that *rapproch* which means a unified attack once their existence is recognized. The remedy for wrong social conditions lies in the hands of the people themselves and no satisfactory substitute has been found for self-analysis and self-help.

Peking Union Medical College

The Rockefeller Foundation has announced the plans for the dedication of the new buildings of the Peking Union Medical College erected by the China Medical Board of the Rockefeller Foundation. The ceremonies will fill the week from September 15 to 22 and will include an international medical conference, to which the scientists from America and European countries as well as the Far East have been invited. At this time Dr. Henry S. Houghton will be inaugurated as director of the College.

In preparation for the meetings and conferences, the secretary of the Foundation, Mr. Edwin R. Embree, who serves as executive officer of the board of trustees of the College, sailed for China in June. During the summer various members of the Boards of Trustees will sail for Peking to be present during the meeting, including Dr. George E. Vincent, president of the Foundation, and Dr. Paul Monroe, chairman of the Board of Trustees. The following medical men have accepted invitations and will be present to take part in the international medical conference: Dr. William H. Welch of Johns Hopkins, Sir William Smyly of Dublin, Dr. R. T. Leiper of the London School of Tropical Medicine, Dr. Francis W. Peabody, Harvard University Medical School, Dr. George De Schweinitz of the University of Pennsylvania, Dr. S. S. Goldwater of the Mt. Sinai Hospital, N. Y., and others.

The Peking Union Medical College had its beginning at the Union Medical College, founded in 1906. In 1916 the property of the earlier school was transferred to the China Medical Board of the Rockefeller Foundation.

The tours started last year by the "Victory Special" in the interest of thrift are being continued in New York as a highly beneficent agency in the improvement of rural community life. Everywhere individual help extends to larger community programs.

Pennsylvania System Uses Posters

At the crossing of Blencir Ave Road over the
 Pennsylvania System tracks at Cincinnati O at 5:40 P.M.
 Feb 9th 1921, automobile bearing license number D403
 State of Ohio, registered in your name,
 was observed to approach and cross the tracks and disregarded
 the usual safety rules of slow speed and looking and listening
 for approaching trains.

Observance of "Safety First" slogan will prevent an
 accident such as is portrayed on reverse side of this card.
 Blue Touring - White Wire Wheels

Ward Combs
 Observer

This automobile was struck by a passenger
 train at the crossing shown, where the usual safety
 rules were not observed by the driver. One occupant
 was killed and four others were permanently injured

International.
 Because of the astounding increase of automobile accidents at railroad crossings this year, the Pennsylvania Railroad, through its Safety First Department is using methods of its own to curb these unnecessary risks. Observers are on the lookout for careless motorists, and pictorial evidence of their lapses are sent through the mails with a warning which they are not apt to forget. Every automobile driver should be a "Safety First" man.

League of Nations Health Committee

The Health Organization of the League of Nations as finally developed, announces as its purpose the following objects: To act as a connecting link between the health authorities of all countries; to act as a clearing house for information concerning everything that constitutes a menace to public health; to form a sort of general staff when an epidemic threatens to overrun a number of countries; to coordinate the efforts of the Red Cross Societies in their work on behalf of "improvement of health, prevention of disease, and the mitigation of suffering throughout the world" as prescribed by Article 25 of the Covenant; to cooperate with the International Labor Office for "the

protection of the worker against sickness, disease and injury arising out of his employment;" to advise voluntary organizations requesting assistance; and, finally, to establish health missions when asked to do so by the League of Nations or by any country belonging to the League.

The membership of the professional Health Committee, which is to act as advisory to the Council and the Assembly in all matters of public health, is made up of twelve experts selected by the Council and private individuals with no regard to anything but their personal ability and standing. To these are added representatives of the International Labor Office and the League of Red Cross Societies designated by those bodies at the invitation of the council.

The Committee as now completed

has the following membership: Dr. G. S. Buchanan, Great Britain; M. Velghe, Belgium; Prof. Madsen, Denmark; Senor Pulido, Spain; Prof. Leon Bernard, France; Dr. Charles Havelock, India; Dr. Alberto Lutario, Italy; Dr. Yoneji Myagawa, Japan; Dr. Calmette, Morocco; Dr. Mimbela, Peru; Dr. Chodzko, Poland; Dr. Carriers, Switzerland; Dr. Luigi Carozzi, International Labor Office; Prof. Winslow, League of Red Cross Societies. The absence of any American name on this list is noticeable.

Food Accessory Factors and the Teeth

The effect of diets deficient in vitamins has been studied from many angles, but in none are the results more interesting than in relation to the teeth. Many writers, notably McCollum and Pitz, Cohen and Mendel, and Zilva and Wells. Mrs. Mellanby has produced irregular teeth in pups by rachitic feeding.

Percy R. Howe, of the Forsyth Dental Infirmary for Children, Boston, Mass., in the March issue of the *Journal of Dental Research*, reports experimental work on animals, chiefly guinea pigs, in which diets deficient in each of the three known kinds of vitamins was able to produce a chronic condition in which calcium was slowly removed from the bony structures—the teeth and the bones—in such degree that carious areas appeared in the teeth, in some cases affecting the entire jaw, producing likewise marked alteration in the ribs and leg bones.

He was able to mark the enamel of the teeth by feeding, alternately, deficient and normal diets.

The same issue contains a study of scurvy and its bearing on the preservation of the teeth undertaken in the physiological laboratory of the University Medical School, Minneapolis, Minn., which shows that there is a rapid loss of calcium from the body of guinea pigs in scurvy. Acid-forming diet (that was also a scorbutic diet) caused a lowering of the alkaline reserve in the saliva in man. Symptoms of deterioration in the teeth appear much earlier than do the clinical signs of scurvy on a scorbutic diet, and the conclusion is reached that in order to maintain the teeth in good condition, the diet must contain sufficient antiscorbutic. The source suggested for the winter supply of antiscorbutic are cold storage vegetables and fruits, canned fruits, tomatoes and rhubarb, and dried fruits and fruit juices.

Economic Interest as a Motive in Health Work

THE motive for public health work during its early stages, down nearly to the present, was the fear of contagious disease. Health work concerned itself with quarantine, pest houses, and vaccination to prevent epidemics. When health work was first introduced into the schools, the motive was primarily protection against contagion. Health workers sought out the signs of contagious disease, vaccinated, and quarantined. The introduction of health work in industry had much the same history. Physical examination and other health work was largely to prevent the spread of contagion. Institutional health work was similarly inspired.

The principal motive is still fear, perhaps, but to it has been added another motive—almost equally strong—the motive of economic interest. It has been found that it is best to have healthy citizens, students, and workers. The protective measures of a few years ago have been enlarged. The public is still actuated by fear of epidemics, but it has also developed interest in strong children growing into robust adults. Preventive and corrective measures, other than for contagious diseases, are assuming larger proportions in public health work. The promotion of physical well being and personal efficiency is the basis of a great deal of the modern plea for health.

Likewise in the schools, health work has enlarged its scope. There is not less protective

work but more work for school efficiency. We hear now of the money lost to the community, through the retardation of children on account of physical or mental defects. We hear much of physical education as a builder of man power and a promoter of efficiency.

In industry it may be said that the economic motive has come to dominate the whole work. Health activity in industry is there because it pays. It pays to have efficient workers. It pays to prevent accidents and disease. It pays to lessen the insurance cost from accidents and the drain upon mutual benefit societies on account of sickness. The motive of industrial efficiency is now uppermost in making physical examinations, in the provisions for industrial medicine, and in the work of industrial nurses.

The combination of economic and humanitarian motives with the motive of self protection is the secret of the vast progress which health work is making in communities, schools, industries, and institutions.

Physical Handicaps and Social Case Work

THE individualization of treatment or "case work," is an underlying principle, in common, of medicine, of teaching, and of scientific employment. This principle is used also by the social case worker, but his specialized service is the treatment of behavior through attention to all the conditions that affect it—physique and health, temperament, desires, training, employment, family, and outside group connections, and other life situations.

To what extent the practice of social work has been concerned with physical handicap, is indicated in references to the subject by leading authorities. In Devine's "Misery and its Causes," two of the three typical situations are described under the captions, "Out of health" and "Out of work." Of the five thousand dependent families in New York City whose condition is analyzed in this study, more than one-half may be identified as presenting problems of physical disability. In Mrs. Alice Willard Solenberger's study of "One Thousand Homeless Men," approximately one-half represent cases of physical disability. A reading of case records of varying lengths occurring in the first one hundred pages of Miss Mary E. Richmond's "Social Diagnosis" shows that approximately one-half of those where the description is adequate for determination of the point are instances of physical disability and possible handicap. In a study, made under the auspices of the Detroit Community Union, of 752 families designated as "trouble cases," having received the

attention of five or more agencies during a given year, approximately two-thirds present problems of physical disability.

The practice of social work may be expected to improve through the development of a procedure in the rehabilitation of physically handicapped persons. While social case workers have had long experience in treating physical handicap, the present rehabilitation movement will tend to broaden their connections with other professional groups. Social workers will have more incentive to make contact with their cases, and to attack community problems, above the poverty line. Local surveys in the interest of the physically handicapped will widen the scope of community self-appraisal, and make a convincing connection between health agencies and programs, on the one hand, and problems of individual need on the other. Additional reasons will develop for correlating the work of schools, medical agencies, industries and welfare organizations. Solutions will be found for many who are now considered to be community liabilities. As rehabilitation work by states and voluntary societies increases, more extensive provisions in the fields of medicine, education and employment will make possible more intensive and adequate service on the part of social case workers.

Industrial Medicine and Civil Leadership

BETTER civic and medical leadership as a by-product of industrial medicine was specially stressed by Dr. Otto P. Geier, in retiring from the presidency of the American Association of Industrial Physicians and Surgeons, in an address printed elsewhere in this issue. He placed emphasis upon the fact that an industrial physician may measure his real capacity not only by the quality of the service that he renders in his industrial clinic, but perhaps even more largely by his educational influence upon: (1) The worker; (2) the plant executives; (3) the industrialist; (4) the local profession; (5) the social worker; (6) the public health officer; (7) the public; (8) state legislation; (9) the medical schools; and (10) the American Medical Association. In having this broad view of his relationship to industry and society as a whole, the industrial physician definitely adds interest to the routine of his daily work.

Dr. Geier urged that the science of industrial medicine affords all of these groups "a better understanding of life in all of its aspects and should eventuate in a type of medical and social philosophy that will make for the highest character of much needed civic and medical leadership."

So-Called Food Poisoning a Preventable Disease

THE "average man"—medical and lay—has peculiar ideas about food and what food does,—that is, when he is sick. To the well, food is counted as one of the joys of living, and little thought is paid to the many steps food takes in its passage from raw material to human tissues. When a few persons are made ill by eating poisoned foods, the occasion is rare enough to warrant newspaper headlines, universal fear, and, usually, complete ostracism of the suspected material. Then the scare dies, a prize fight or a divorce scandal heads the front pages,—and the world remains as ignorant as before about so-called "food poisoning."

In another column of this issue we are fortunate in being able to present a comprehensive and scientific abstract of the present status of poisoning by food. Dr. Street emphasizes the comparative rarity of serious illness arising from poisoned food, quoting Rosenau's statistics that in twenty-two years 150 persons are recorded in the United States as having been made ill by botulism, with 111 deaths. The possible sources of trouble in the raw material, in factory, storage, distribution, and, finally, in the home of the consumer, are so multiple that it is really surprising to find so few substantial cases of illness produced by diseased food. Naturally, Rosenau's statistics include only those cases reported; there is not and never has been statistical or scientific proof that such a thing as "ptomaine" poisoning exists. Rosenau, Savage, Chapin, and Vaughan are quoted in emphatic protest against the conception of ptomaine,—a protest which we should like to see scattered broadcast. Too many individuals still labor under the ptomaine delusion, too many diseased appendices, gall bladders, or what not, are overlooked—often until too late—because of the traditional belief in the danger of a perfectly prepared can of salmon, or a perfectly fresh lobster!

Food poisoning does occur, but Street believes that the general term should be replaced by more definite etiological statements. Food may be injurious because of natural poisons, animal parasites, plant parasites, toxins, and in other less important ways. Food may become infected—generally with a bacillus of the *Gaertner* type; or become poisoned with a toxin such as that produced by the *Bacillus botulinus*. Meat is the food most likely to become infected, although milk, cheese, even vegetables, may carry the infection. This type of poisoning appears most commonly in prepared meat foods and is the type often erroneously called "ptomaine." It is always, how-

ever, an infection, and may occur ante-mortem through infection from without. Being an infectious disease of known etiology, it is likewise a preventable disease! Extreme care in marketing, with *thorough* cooking just before serving, could prevent most outbreaks of poisoning from this group.

Food poisoning by means of toxins has received attention lately because of the cases of botulism due to canned olives and spinach so well reported in the daily press. It is important to note that neither this type of "toxic" food, nor the infected food can be detected by the senses in all instances. The bacillus which produces *botulism* apparently grows anywhere and may be found in animal as well as vegetable food. Street believes that home packed foods have been responsible for a large proportion of the cases thus far reported. This is not an argument against home packing, but is a very strong argument in favor of the employment of the utmost care and the greatest scientific skill in food preparation.

General Hospitals and the Care of Tuberculosis

THE National Tuberculosis Association in 1916 passed a resolution urging general hospitals, "for humanitarian reasons and purposes of instruction," to provide separate wards for the care of cases of tuberculosis. Five years later, at the recent Boston meeting, the American Medical Association adopted a resolution recommending similar action because the present practice of denying admission of tuberculosis patients to general hospitals "has resulted in the relegation of tuberculosis largely to specialists, to the great detriment of the tuberculosis patients, who are thus compelled to seek in special places the necessary medical skill, and of the general practitioner of medicine, who is thus deprived of the opportunity to acquaint himself with the diagnosis and treatment of tuberculosis."

The United States Public Health Service in an authorized statement endorses and commends this action of the American Medical Association and notes with interest the "very marked change in medical sentiment." It anticipates remarkable advance in popular knowledge of tuberculosis as a result of the establishment of this new policy. "Visits to the hospital will familiarize members of the patient's family with sanitary precautions, such as the sputum cup, which commonly horrifies them and is soon given up by home patients."

The value of caring for tuberculosis patients in general hospitals, in the promotion of medical and nursing education, is universally recognized, and it is hoped that the new suggestion will be

widely followed. The Jersey City (N. J.) Hospital has recently opened a large tuberculosis ward and placed it under the medical director of the county tuberculosis hospital. Such fortunate relations should be generally encouraged.

An important point to be considered in connection with this new plan was brought out at the 1921 meeting of the National Tuberculosis Association in a resolution disapproving of the care of early cases in general hospitals and urging the admission of advanced cases only. The reason given is that early cases fare better in institutions outside of cities; also the depressing mental effect of association with advanced cases should be avoided.

Studies in Physics as Applied to Hygiene

THE study of the physical problems underlying the hygiene of clothing and housing, so brilliantly initiated by Pettenkofer fifty years ago, has been relatively neglected, and careful researches along these lines are always welcome.

A study by Grabham¹ of the physical characteristics of various textile materials suitable for clothing in the tropics is quite in the Pettenkofer manner. By reading thermometers placed under layers of cloth of various colors and textures, and inside cylinders painted with different paints, the author obtains detailed quantitative confirmation of the important influence of color on absorption of heat rays recorded by Benjamin Franklin at the close of the eighteenth century. The differences are surprisingly great, the thermometer under white drill rising between 11 a. m. and 1 p. m. to 57.6 degrees C., as compared with figures ranging from 72 to 76 degrees for various grades of khaki and with 85 degrees for thin black lining. Porosity was also tested with an ingenious air pressure apparatus, an old worn piece of calico giving the most favorable results, but evaporation was about the same with both calico and khaki. The main practical deduction is obviously the great superiority of white to khaki clothing for warm climates, a superiority even greater than would offhand have been expected; but the technic used in these studies, while in some respects tentative, is worthy of more general development and application.

An exhaustive report on studies of the rate of heat conduction through various building materials carried out in the laboratories of applied physics of the Technical High School at Munich²

1. Grabham, G. W. Some Factors in Thermal Sanitation in the Tropics. *Journal of Hygiene*, xix, January, 1921. p. 245.

2. Knoblauch, O. Rasch, E. and Reiher, H. Die Wärmeleitfähigkeit von Bau- und Isolierstoffen und die Wärmedurchlässigkeit neuer Bauweisen. *Gesundheitsingenieur*, 1920, Heft. 52 p. 607.

constitutes another very valuable contribution to physics as applied to hygiene. These experiments have been going on since 1912, first with a small laboratory testing apparatus and later in a small experimental building, the two methods yielding closely concordant results, which should be of great value to the student of the hygiene of building construction.

Capacity and Environmental Factors in Efficiency

THE physical work performed by an individual will obviously depend upon two sets of factors, physiological and environmental; and the remarkable recent stimulation of research in industrial physiology all over the world is throwing light upon both problems.

The work of Dausset and Boigey in Paris, reported in *Paris Médical*, April 16, is illuminating in regard to the analysis of inherent differences in capacity. Using a special form of "universal goniometer," they record the extent and frequency of repeated movements of various muscles and report characteristic curves for individuals of four different neuromuscular types. As demonstrated by Masso and Yoteyko, these curves exhibit a plateau followed by a descending curve as fatigue sets in. Dausset and Boigey recognize:

(1) A strong and nervous type showing a long plateau followed by a slow decline.

(2) A type, muscularly powerful but deficient in nervous endurance, showing a long plateau followed by an abrupt decline.

(3) A type, of slight muscular power but marked nervous endurance, showing a short plateau with a slow decline, and

(4) A type, weak in both muscular and nervous power, with short plateau and abrupt decline.

The authors believe that such a classification should be of value in selecting forms of physical exercise (and presumably forms of industrial employment) suitable to a particular individual. It is unlikely that the facts will prove quite so simple as such an analysis would indicate, but the work is well deserving of repetition.

On the environmental side a very valuable contribution comes from the Rand gold mines of the studies of A. J. Ornstein and H. J. Ireland, published in the March issue of the *Journal of the South African Institution of Engineers*. These authors report striking confirmation of the work of the New York State Commission on Ventilation in regard to the influence of high atmos-

pheric temperature on the performance of physical work. The South African observers used ergometers simulating certain operations performed in gold mining and measured the cooling effect of the atmosphere by the use of the katathermometer.¹ Considering efficiency with a dry katathermometer reading of 6 as 100, the work performed fell to 50 with a katathermometer reading of 1. Electric fans blowing on the subjects caused an increased performance of 32 per cent in one case and of 46 per cent in another; and the authors estimate that under actual working conditions in the mines there is a 21 per cent loss in efficiency as a result of high temperatures.

Immunization Against Typhus Fever

THE genius of human nature for plucking the flower, safety, from the nettle, danger, is not only proverbial but a very vital fact. Even the tragic disorganization of health administration in Russia furnishes an example; for the alarming increase of typhus fever in that distracted country has offered the stimulus and the opportunity for experiments on immunization with the serum of patients which may prove to be of real significance and value. The British Mission to South Russia during the epidemic which completed the disintegration of Denikin's army, used a vaccine prepared by taking blood from a donor in the fifth to the seventh day of the disease, defibrinating, adding carbolic acid and heating for one hour at a temperature of 57 to 58 degrees C. Three doses of 1, 2, and 2 c. cm. were given at intervals of five to seven days. The procedure is described by J. M. Mitchell and G. P. N. Richardson in "Some Notes on the Prophylaxis of Typhus Fever" in *The Lancet* of April 9, 1921. Among 195 vaccinated persons, only one case occurred, while among eight hundred unprotected persons sixty-nine cases developed, with thirteen deaths. One Russian bacteriologist, working in the Mission Hospital, became so enthusiastic that after a heavy dose of protective vaccine (5 c. cm.) he inoculated himself with 1 c. cm. of fresh blood from a patient on the fifth day of the disease. This ultra-rigorous test resulted in a severe case of typhus.

The pioneer investigators of this problem in Soviet Russia itself have been Liotropov, Ilatogorov and Marzenevsky, reported by B. Sokolov in "Medicine in Soviet Russia," *The Lancet*, April 23, 1921. Their methods are essentially the same as that described above, although Ilatogorov insists on the importance of a polyvalent serum and uses larger doses. He concludes that the vaccine

1. For a discussion of the relation between katathermometer and temperature readings, see C.-E. A. Winslow and E. L. Hewitt; Relation between Katathermometer and Thermometer readings under ordinary indoor conditions. Heating and Ventilating Magazine, xviii, March, 1921, p. 27.

decreases susceptibility to one-fifth of its normal amount. Both the vaccine thus prepared from the blood of a patient at the height of the disease and the serum from recovered patients have been used by Ilatogorov in typhus therapy with promising results.

The conditions under which experiments are carried out in Moscow and Petrograd today are naturally such as to make careful scientific control exceedingly difficult. The opportunity of dealing with large numbers of typhus patients in the immediate entourage of medical institutions of relatively high development has, however, been an unusual one; and the results obtained are suggestive and interesting.

THE *Boston Transcript* comes down hard on the state senate of Massachusetts for passing a bill which would practically nullify the law for vaccination against smallpox. "The bill provides that the requirement of the law shall not apply in the case of any child who presents a written statement signed by a registered physician, or by parent or guardian, to the effect that the writer believes that vaccination would be injurious to the health of the child." In other words, the judgment of parent or guardian, quite apart from the opinion of a physician, must be accepted as controlling in the matter of vaccination. "There should be cast against it a vote so large," says the editorial, "as to put an end to the attempt to remove a precaution which is regarded by the great majority of the medical profession and by an enlightened body of public opinion as a necessary measure of protection against a deadly disease."

THE telephone has sprung into such common use during the last fifteen or twenty years that health workers have questioned the possibility of the transmission of diseases of the respiratory type through direct contact with infected transmitters and receivers. The results of an interesting series of experiments on the bacterial content of telephones are quoted by Saelhof in the second number of the *American Journal of Hygiene*. Cultures from the transmitters and receivers of a series of public telephones were taken at various periods, before the influenza epidemic of 1919-20, during the epidemic, following the epidemic, and in 1920 during the second post-epidemic period. The telephones were classified into three groups: clean, filthy, and very filthy. Various pathogenic bacteria were isolated from these telephones but the data presented are of such nature that no conclusions regarding frequency of transmission can be

drawn. The telephones during the influenza epidemic contained more pathogenic organisms than during the interepidemic periods. As stated by the author of the study, "It is probable that the danger of infection from this source is light."

In a series of experiments Saelhof was able to show that organisms lived two or three days longer on filthy transmitters than on clean ones. The infectivity of a mouthpiece would therefore vary inversely with its cleanliness. Frequent sterilization of telephones by thorough cleansing followed by immersion in a disinfectant, and teaching of the public in the hygienic use of the telephone are recommended as the means of minimizing the danger from the use of the infected telephones.

THE National Conference of Social Work, which held its annual meeting in Milwaukee, June 22-28, again proved by its program that health work to a large extent underlies social work. The conference regularly devotes two of its ten sections entirely to health and in addition a goodly proportion of the other sections was given this year to health problems. Nearly half the program had a direct bearing upon health problems. Such facts should tend to bring the physicians, health workers, and social welfare agencies into closer relationship in investigation and research, and in the administration of social and health activities. Industrial and economic problems enter into the picture as well as the facts brought out in the organization of family social work, and a more constructive program may be expected to evolve from the correlation of activities. Robert W. Kelso of Boston is the new president of the National Conference. The next meeting will be held in Providence, R. I., in 1922.

THE acceptance by Dr. Lee K. Frankel of the work of planning a welfare department for postal employees, which was recently announced by Hon. Will Hays, Postmaster General, has been received with enthusiasm by health and welfare workers. Dr. Frankel's experience in developing the health and welfare work of the Metropolitan Life Insurance Company will be a practical guide in the new undertaking.

THE National Convention of the American Red Cross scheduled to be held at Columbus, O., in October has for its purpose the wide consideration of the permanent program of the Red Cross. It will be the biggest thing in the form of a Red Cross gathering ever held.

The Educative Potential in Industrial Medicine*

Better Civic and Medical Leadership
Is a By-Product of Industrial Medicine

By OTTO P. GEIER, M.D., CINCINNATI MILLING MACHINE COMPANY, CINCINNATI, O.

THE final test of any organization such as the Association of Industrial Physicians and Surgeons, is perhaps the amount of influence exerted, not upon its members alone but upon society at large. In the last analysis, therefore, its value depends upon educational influence.

Let us take a brief review, therefore, and see how an objective of general educational value might best be accomplished. Fundamentally, such an estimate must begin with a thorough self-analysis on the part of constituent members. It is high time that the industrial physician determines just what position in the industrial sector he should properly command. To reach an intelligent conclusion in this regard, he must have thorough understanding of (1) The function of industry and its relation to society; (2) the scope of an industrial relations department; and (3) the integral factors of such department, viz.: employment, training, health and sanitation, safety and social welfare.

Self-Appraisal Called For

When the industrial physician has a thorough comprehension of the field of work of which his is a part, when he has measured his knowledge and his capacity to handle and fit his work into all phases of personnel work, he will for the first time be in posi-

The final test of industrial medicine is the value of the service it renders. The capacity of the industrial physician to serve is measured by the man, his preparation, his vision, and, most of all, his attitude toward his job.

For the industrial clinic is no circumscribing individualism, but an illuminative social study, and the development of anything like adequate service evolves a social philosophy which affords the drive toward civic and medical leadership.

tion to use himself 100 per cent in medical service to industry.

The most pathetic sight today is to see an industrial physician of fair intelligence, holding a circumscribed, small niche in personnel work, with no dignity attached to his office—an underling to men of inferior education, intelligence, and capacity. An inclusive educational program, therefore, needs to begin with:

(1) Self-education.—A thorough knowledge must be attained of the present working methods and literature of industrial hygiene, sanitation, and safety. Occupational diseases must occupy an important position, and the efficient treatment of injury and illness as it affects the worker must be emphasized.

(2) The education of the worker to the free use of these facilities with

an improvement in his personal hygiene—including dental hygiene, is an essential corollary, and the better selection of physicians and the use of consultants are called for.

(3) The educational program would reach the executives, superintendents, general foremen, and foremen, urging the dollars and cents value of good health, with special emphasis on the prevention of disease and accident.

(4) This would include the education of management, impressing boards of directors and stockholders with the economic value of good health as a factor in production, industry's responsibility toward community health and living conditions, and legislation looking toward improvement in that direction.

(5) Such a program would educate the local profession, making it sympathetic to the efforts of industry to improve health, to secure its better attention to the industrial workers' health problems, benefiting medical science by contributing the accumulated records of the industrial clinic. The importance of regularly appearing before county medical societies with case reports cannot be overstated. These should be so written as to emphasize not only the scientific handling and care of the case but should stress the social and economic methods that obtain in the industrial clinic.

(6) A program of this kind includes educating the social worker so as to supplant the social reformer with his ill-considered and unwise

*Address as retiring president of the American Association of Industrial Physicians and Surgeons, Boston, Mass., June 6, 1921.

agitation. Because of the fact that the medical profession as a class does not take an active, energetic part in public discussion, the laity more and more is assuming the directing hand in planning legislation in health matters. Compulsory sickness insurance would be operative in several states of the Union today, I believe, had it not been for the contributions toward the discussion of this subject made by the industrial physicians whose work has enabled them to study mass health problems and who know, therefore, how ill considered were the promises of the proponents of sickness insurance.

(7) The health officer also needs to be enlightened in matters of industrial hygiene, stimulating him to an interest in the subject of factory sanitation, encouraging him to use his weekly bulletin for the promotion of this work.

(8) Perhaps most important of all is the process of educating the public through local civic organizations to a better understanding as to the fundamental value of community and state health programs, with the insistence that these shall be administered free from partisan control, and adequately financed.

(9) Direct influence needs to be brought to bear on state legislators through local representatives, studying all legislation—presented either by labor or capital—which affects the welfare of the worker. The industrial physician should have first hand knowledge of compensation laws, occupational disease laws, factory workshop inspection laws, so that he may be in position to present facts not controvertible when legislation affecting these things is up for discussion.

Socialize Teaching Profession

(10) If any or all of the above educational facilities properly belongs to the industrial physician, if they are at all worth while, then it is doubly the obligation of the industrial physician to bring home all of these facts to that part of the medical profession which has charge of our medical schools and which by virtue of that fact is determining the type of medical men that are to come out of our medical colleges. The medical colleges are molding the men today who will control the profession of tomorrow. The graduates will either be individualists, unfitted to cope with society's problems, or they will be taught to think in terms of the community, in terms of society as a whole, and thereby fitted to become leaders of society's progress.

(11) Finally, the collective action of all industrial physicians, bound together as they are in this Association, should be such as will influence our parent organization, the American Medical Association, to accept this new specialty as fundamental to the progress of medicine in this industrial era; that it may assist this Association more vigorously in promoting the educational propaganda that is herein outlined. For, if the American Medical Association can be made to take the broad vision of its larger responsibility, if it can be made to realize that the general application of our present accumulated science for the prevention and cure of disease is ten to fifteen years behind this knowledge, if it will use the industrial approach to help bring forward the economic and social aspects of medicine, then will the medical profession come out of its isolated position in state and national affairs, it will hold its proper position in the councils of the country and gain its deserved place among those who must plan today that this rich nation tomorrow may afford its citizens long years to live, a decent place to work and to earn, to the end that each citizen may be a most productive independent, contented unit of society.

In relinquishing the presidency of this Association, I wish that I might crowd in my few final words all the hopes and aspirations that I hold for the future of this Association. This much I know: The strength or weakness of our position as an Association will be in direct relation to the breadth of view that each member of this Association holds towards his particular job and his specialty at large. In outlining our relationship to the broad educational medical field, I have attempted to supply at least the text for our further advances into industrial and economic fields.

If the majority of the members of this Association are content with "puttering around" within the circumscribed area of their industrial clinics, satisfied to do the menial things with no conception of the true value of their work in the field of industrial relations, then of course will all of the foregoing have been said in vain. It must be apparent, however, that the very kind and quality of industrial medical service should afford the members of this Association a better understanding of life in all of its aspects and should eventuate in a type of medical and social philosophy making for the highest character of much needed citizenship and medical leadership.

Frankel Directs Postal Welfare

Announcement is made of the appointment of Dr. Lee K. Frankel as director of the Welfare Department for postal employees, which is being fostered by the Honorable Will H. Hays. The project is very far-reaching in its scope and of outstanding importance in the health annals of the country. There is no one in the field of public welfare who is by business insight and experience better fitted successfully to engineer an undertaking of this kind. The development of the Welfare Department of

the Metropolitan Life Insurance Company under his directorship is sufficient earnest of his capacity to handle the situation.

Dr. Frankel is only loaned by the Metropolitan Life Insurance Company for the period necessary to make a survey of the situation. Dr. Frankel expects by the Fall he will be able to make a report of his study of the situation and outline a plan of what should be done and indicate what it appears possible to accomplish.

Institute for Graduate Nurses

The Michigan State League of Nursing Education has just completed a two weeks institute for graduate nurses interested in hospital administration and training of student nurses. One hundred seventy-six graduate nurses from seven different states attended. Lectures, clinics, demonstrations and round tables were held on the various subjects pertaining to nursing activities.

The Medical Department in Industry

Employees Are Entitled to the Best Possible Service, but the Profit That Accrues Is Mutual

BY MARVIN Z. WESTERVELT, M.D., MEDICAL DIRECTOR, WINCHESTER REPEATING ARMS COMPANY, NEW HAVEN, CONN.

SHOULD the question be asked, "Why a Medical Department in Industry," we would give as one of the reasons that in these days no city, town, or even small village would be thought to be complete in its organization unless some provision were made to look after or supervise the health and sanitation of the community. Then why not an industrial plant, often with the population of a small city in its employ? This supervision may be in the form of a completely organized board of health as in larger cities, or simply a health officer as in the smaller towns or villages; in industrial plants it takes the form of a medical department which may be more or less elaborate as needs may dictate. The foregoing is simply one, general reason for a Medical Department in industries. Let us particularize a little, and in so doing we feel we can best cover the ground by referring to our own work at the plant of the Winchester Repeating Arms Company. By doing this we can state facts and figures secured at "first hand" and not rely upon those gained from information less concrete with the attending likelihood of unreliability. For convenience in handling the subject has been divided into four chief divisions as follows: I. Its field; II. its function; III. its relationship to other departments, and IV. its future. These chief divisions have been further subdivided somewhat as follows:

I. Its Field.

- a. General hospital work.
- b. Sanitation and hygiene.
- c. Health engineering.
- d. Consultant and advisory.

II. Its Function.

- a. General Hospital Work.
 - 1a. Caring for sick and injured employees.
 - 2a. Diagnosing and referring of cases.
 - 3a. Performing or assisting at all operations.
- b. Sanitation and Hygiene.
 - 1b. Detecting and preventing spread of disease.
 - 2b. Sanitary inspections; toilets, wash-rooms, drinking water, etc.
 - 3b. Hygiene inspections; air, light, ventilation, heat, etc.
- c. Health Engineering.
 - 1c. All of a and b.

- 2c. Physical examinations.
- 3c. Recreation, cafeteria, etc.
- d. Consultant and Advisory.

III. Its Relationship to Other Departments.

- e. Coordinate with all, subordinate to none.
- f. As a "production" factor.

IV. Its Future.

These subdivisions will be considered in the order given.

General Hospital Work

1a. *Caring for sick and injured employees.* This, we presume, is the chief reason for a medical department in any industry. At least, it has been so considered in the past; but as the work has developed other activities have taken on so much importance that it is now an open question as to whether the mere doing up of cuts and bruises is the chief function of the department. However, that this still continues to be a large part of the work, if not the most important will be borne out by the following figures.

During the year 1920 the average monthly "population" of the Winchester Repeating Arms Company plant was between eight and nine thousand. During the year the activities of the hospital staff were divided up as follows:

Caring for 13,456 new injuries.
Making 28,986 re-dressings.
Ministering to 10,091 cases of sickness.

Taking, developing and interpreting 121 x-ray plates.

Making 213 physical examinations.
Transferring 146 injured or sick employees to their homes.

These constitute simply the activities in behalf of the sick and injured employees and do not take into consideration the activities that will be spoken of under other headings. Taking just those activities enumerated above we find a total of 54,869 ministrations, a weekly average of 1,056 and a daily average, including Sundays, of 151. This number will equal that of the average hospital in any city of eight or nine thousand population, or even larger. Do not these figures prove the existence of this Medical Department justifiable; and, if this one, then why not others?

We would call attention to one fact

as disclosed in the foregoing figures that goes a long way to prove the advantage,—in dollars and cents if it seems preferable to express it in that way,—in having a medical department in industry. Note the comparison between new injuries and re-dressings—13,456 to 28,986 or only 2.15 re-dressings per new injury. This low average we do not attribute to the efficient work of the hospital staff but rather to the fact that by prompt and painstaking care of the smaller injuries we are saved the larger and long-drawn-out infections. "The stitch in time saves nine," is certainly exemplified right here. What this means to the employees in the saving of lost time will be touched on later. What it means in the saving of serious infections may be judged from the fact that from January 1, 1918, to January 1, 1921, we cared for 54,958 new injuries and in only two cases did an employee lose any portion of his body due to an infection. In both cases it was an index finger that was lost, the first one, becoming tuberculous in character, attacking first the joint and then the bone, was so far advanced when first reported to us we could do nothing but advise amputation, although, with the patient's consent, we did try to save it. The second case remained under our care only three days, then went to his own physician who, after one month's treatment decided he would better amputate, but the patient "moved on" to a third physician who finally did amputate. A loss through infections amounting to 0.00003 per cent for a period of three years is surely the strongest kind of an argument that could be offered in favor of a medical department in industry, for it is only by having the facilities at hand to attend at once to not only the big injuries, but the little ones as well, that such an extremely low average could be attained and maintained.

In cases of sickness we simply render emergency treatment, the patient either returning to their work or are transferred to their home and referred to their own physician. Rest rooms are a part of the hospital suite. Here the employee may lie down for a

A first aid room serving an industrial plant of nine thousand people must be equipped for major work, but its chief service is in the prompt care of every minor injury and disorder which constitutes the best part of preventive medicine.

period of time if not able to return to his work at once.

2a. Diagnosing and referring cases.—We have just spoken of referring our "sick" cases to their own physician. In addition to these, employees come to us for advice or examination. These cases are gone into, the history and symptoms secured and the patient then advised as to the best course for them to follow, which may be to simply see their own physician for a course of treatment or to see a specialist where it is evident that such a one would be of more service than a general practitioner. In addition to these cases, certain classes of injuries or end results of injuries require the services of one specialist or another; or possibly hospital care and treatment is called for. In all these cases we act as a clearing house, performing a selective function and assigning the case to the proper physician, surgeon, or institution for care or treatment. It can readily be seen that this would not be the least important of our functions and often means much to our employees. If left to their own selection the men often drift from one form of treatment to another, frequently following the advice of the last friend to whom they happened to retail their troubles, and all with little or no beneficial results. In fact, a great many cases of total or partial permanent disability might have been avoided if wisely and correctly directed and cared for in the

beginning. These disabilities are not only a hardship on the patient because of a lowered earning power and a greater or less disfigurement, but it means also a needless waste of dollars and cents to the employer, possibly in compensation, but surely in a loss of productive power.

3a. Performing or assisting at operations.—In our own hospital at the plant we are prepared to do all operations that are usually done under a local anesthetic, including amputations and those of a like nature. Those cases requiring a general anesthetic are removed to one of the city hospitals. The head of the Medical Department performs all operations at the plant hospital and either performs or assists in performing all of those referred to the city hospitals. In addition to this, he holds himself in readiness to be present,—and assist, if so requested,—at any operation on any employee, whether this operation is made necessary because of some injury received at his or her work or not. He will also be present and assist at any operation on any member of any employee's family. This latter is done simply because by so doing the employee comes to his work as usual, knowing there will be some one at the scene of operation who will be of service where he could not be and who will bring him a report at the earliest possible moment as to the outcome of the operation and the condition of the patient. Thus,

the employee's daily wage is saved to him and his anxiety is no greater, if as great, as if he himself were sitting in the waiting-room at the hospital awaiting the result of the operation. On the employer's side, the man's work for the day is conserved and the consequent loss in production is saved.

Sanitation and Hygiene

1b. Detecting and preventing spread of disease.—This is done by daily inspections throughout the plant, by investigation of cases reported to us by foremen or fellow employees and by examinations of employees who voluntarily report to us because they "do not feel well" or, "while dressing this morning a rash was noticed somewhere on the body." When a case of infectious or contagious disease is found, the employee is taken home at once and not allowed to return until a clean bill of health is furnished by the attending physician. Even suspicious cases are sent home and kept under observation for twenty-four or forty-eight hours. In cases of vermin infection the person is advised as to a form of treatment to rid themselves of the "critters" and the case is followed up until we are sure that satisfactory results have been attained. These cases are allowed to remain at their work but every precaution is taken to protect their fellow employees.

2b-3b. Sanitary inspection and Hygienic inspections.—These two headings can be considered briefly together, the character of the work being the same and is performed in a like manner in both instances. The entire plant is "covered" twice daily by members of the Medical Department staff. All cases of defects are reported at once by telephone to the hospital, and from there relayed to the proper department for attention. Once each month the head of the Department makes a personal tour of inspection covering the entire plant. In addition to this he personally investigates all cases calling for special investigations and recommendations. The inspections take in the heating, lighting, ventilating, toilet and drinking facilities, wash and locker rooms, cafeteria and recreation centers. It is only by an eternal vigilance, exercised by a department "on the grounds," in some such manner as we have described, that an industrial plant, especially one of any size at all, can be kept a healthy and safe place in which to work.

1c. General and special.—In the past the worker at the machine or

bench has received less thought than the machine. We have regarded the nature of the machine, its capabilities, its physical well being and almost entirely disregarded the man operating it. Now we are beginning to realize that the individual worker is at the bottom of all the machinery of production. This being true, why should we not have our health engineers as well as our manufacturing engineers, civil engineers, or industrial engineers or any one of the dozens of other engineers? All of the work we have spoken of thus far would properly come under the functions of a health engineer. But there is still another activity which, while implied in the foregoing, requires the special emphasis given it in our next sub-division.

2c. *Physical examinations.*—There is not a machine set up in this plant, and I doubt if there is in any other plant, that is not first thoroughly inspected, examined and even tested. Then why should not the man who is to run it be also examined? The stock that goes into the making of the products of the plant is submitted to inspections and tests. Then why should not the man be who is going to get out these products? No matter how perfect the machine or the material, if the man back of them is not physically fit there is bound to be an unnecessary economic loss and waste. And then, too, in inspecting a machine it may be found to be defective simply through a loose part. The tightening of this part renders the machine capable of the work it was intended for. In examining a prospective employee he may be found unfit to do the work he seeks because of some minor defect which, upon being corrected, renders him capable of doing that work. On testing a lot of steel it may be found to fall short of specifications required for certain products and yet sufficiently good for other products. On examining an applicant he may be found to be below the requirements for a certain job but all right for some lighter task or different class of work. If the defective machine or material is not immediately thrown out upon the scrap heap, then why throw the defective man out upon the industrial scrap heap without first seeing if there is not some place that he can fit in,—some work that he can do?

Physical examinations should not be made with the idea of rejecting all those who happen to be below normal, physically. It has never been our purpose to "cull out" the unfit, but rather to find a place where the unfit

will fit. Finding a job for every man and fitting the man to that job will tend to conserve the man's energy, promote contentment, increase production and lessen accidents. Through examinations and re-examinations, the early detection and possibly the elimination of organic or functional diseases is rendered more likely and more possible. The extent to which examinations should be practiced and the frequency of re-examinations depends upon the character of the work, the conditions under which the work is performed, the previous history of the applicant or employee and the conditions found in the first examination. Physical examinations are not only practicable but they are the cheapest form of health and life insurance that any person can invest in. They are also a mighty good investment for the employer in that they tend to increase production, cut down the labor turnover and reduce the cost of compensation.

3c. *Recreation and cafeteria.*—Two important factors in keeping employees healthy and happy are the food and recreation they secure. It is to the management's interest therefore, to have supervision over these two factors, at least during the hours of employment. As both food and recreations have such a direct bearing on the health of the employee, they should come under the direction of the Medical Department. Well balanced meals can be worked out so that a substantial lunch or dinner can be

served at low cost. And then, remembering that "all work and no play makes Jack a dull boy," a program of dances, games and other forms of recreation can be worked up to fill in the extra time during the noon hour. The benefits of these activities all come back to the management in the form of increased production, contented employees and a strengthened spirit of loyalty. Grouches become so scarce that a "grouchee" is almost an unknown person.

Consultant and Advisory

We have already referred to the fact that employees come to the hospital for examinations and advice,—not because they are really sick, but "just don't feel altogether right." Physicians and nurses on the Medical Department staff are always ready and willing to give of their time, services and knowledge to the employee in trouble, be it mental, physical or domestic in character. It makes no difference whether the trouble was caused by their work or not, or whether it has to do with conditions in or about the factory or offices. Whatever or wherever the source of worry it is probably proving a hindrance to that person's best productivity and is therefore, a fit subject for our attention. A simple word of good cheer or friendly advice may, and often does go a long way toward producing contentment;—without contentment no one can do their best work. This is why we try to heal

The hospital force during the year of 1920 cared for 13,456 new injuries, made 28,086 redressings, and ministered to 10,091 cases of sickness. Supervision is extended when desired to the families of employees.

Provision in matters of health supervision has resulted for this firm in a loss through infections amounting to 0.00003 per cent for a period of three years. It is not only care for big injuries, but for the little things as well, that maintain such an average.

and restore not only the physically sick but the mentally sick as well. The relationship of physician and patient is not lost sight of simply because we happen to be a part of an industrial organization. These people form our clientele just as surely as do the patients of any physician; we have their interest and welfare just as much at heart and treat their confidences just as sacredly. It is only by adhering strictly to these principles that any industrial Medical Department can expect to do its best work.

Relates to Other Departments

c. Coordinate with all, subordinate to none.—"They are many members, but one body," and just as it was proved in Scriptural text that each member was dependent upon the other members, so is it true that every department in an industrial plant has need for the services of the Medical Department and the Medical Department has need for the cooperation of all other departments. In some industrial plants it has been and is the plan to charge the cost of the hospital work back upon the department from which that work originated. This is done on the theory that if a machine or tool breaks the repairs are charged up to the shop where the break occurs. This being so then why not, if an employee is injured and needs "repairing" charge that up to the shop wherein the injury was received? In theory this sounds good, in practice

we do not believe it to be so good. Our aim has been to have *every* employee report *at once* to the hospital for *every* injury, no matter how small that injury. By doing this we have been able to keep down our re-dressings as already shown and reduced our lost time accidents as will be shown. We do not think it probable that a foreman, if he knew the cost was to be charged up against his department, would be so willing to send all of the little injuries to us. Would he not be very apt to say, "Oh! that isn't worth bothering with, never mind it?" Of course he would. "He is being continually admonished to keep his costs down and quite naturally he would take this method as one to help him accomplish such an end. Believing this to be true we have thought it advisable not to put this obstacle in the way of having the employees come to us. The entire work of our department is borne as a departmental expense, as is also that of the Compensation Department. We believe that rather than put any obstacle in the way of a full and free cooperation on the part of the foremen and heads of the departments, we should do everything possible to encourage such a relationship.

f. As a production factor.—As a "production factor" we do not mean to intimate or infer that we go out into the factory and help run the machines or inspect the parts. Nevertheless, by keeping the men on the job or restoring them to their jobs at

the earliest possible moment after an injury, we certainly do enter in as a "production factor" and one of no small importance at that. To what extent does a Medical Department in industry discharge their obligations on this point? We will answer this by quoting from our own record. We have already told you that during the year 1920 we cared for 13,456 new injuries, and of course every new injury is a potential time loser. As a matter of fact, however, out of our 13,456 new injuries, there were only 245 that were actually time losers and only 112 of these lost sufficient time to become compensation cases,—which means the loss of seven days or more. In other words, only 1.82 per cent of our injured employees were compelled to lose any time at all on account of their injuries and only 0.83 per cent lost as much as seven days. Since the installation of a full-time physician in charge of our medical work, the lost time accidents have been reduced 81 per cent and our compensation rate has been reduced 60 per cent. Is this not rather convincing evidence that a Medical Department is a factor in keeping up production? Would it not appear that such a Department is worth while in industry?

Future of the Service

Industrial medicine is no longer in its infancy, although it is not yet full grown. It has proved itself to be as much a "specialty" in the field of medicine as are the various other specialties that have gone before it. It has proved also, that it really has a place in the industrial field. The old time company doctor, with his limited vision and often crude methods, has been replaced by the industrial physician with his ever broadening vision and up-to-the-minute methods. The curative phase of the work is giving way to the preventive. Every Industrial Medical Department is, or should be, a community health center in the largest meaning of that term. The lessons in sanitation and hygiene taught here are carried into the homes and must in turn, affect the life and health of the entire community. By keeping the workingman or woman healthy and happy on the job, the same health and spirits will radiate outside and make for better contentment and better citizenship. By eliminating to a large extent, the industrial human scrap heap, finding a job that even the lame, the halt or the blind can fill, poverty and dependence will be that much lessened. By reducing the stupendous sum represented by lost time on the part of

injured employees and the consequent loss in production, this sum having to be added to the cost of production, and this in turn to the cost of living.—by reducing this, the buying power of the dollar is that much increased and the cost of living is correspondingly decreased. By all these means and more besides, the Medical Depart-

ment in Industry has proven its worth in the past. By continuing along the same lines it will, in the future, be more and more recognized as a source of help and benefit to the individual, a department of indisputable worth to industry and a power for good to the whole community. Through service it has won its place,

by continued service it shall not only maintain that place but go forward to an even larger one. Its future is assured,—let us who are engaged in the work, or those who may take up the work, never lose our visions of what that future should be nor fall short of our best efforts to attain that goal.

Flat Foot as a Problem of Industrial Surgery

Concomitant Predisposing Constitutional Conditions Are Always to Be Looked For

By R. B. BETTMAN, M.D., CHICAGO, ILLINOIS

THE weak foot is a disability which greatly handicaps a large class of workmen, and may completely incapacitate a few. Much can be done by the industrial surgeon to alleviate this condition and at the same time keep the worker on the pay roll.

"Flat Foot" a Misnomer

The weak foot, or flat foot, or "falling arch"—both of these terms being misnomers—occurs in workers who stand at their work for long hours, or who walk continually on hard factory floors. It is apt to be a disease of the new employee, of the worker who is transferred from a sedentary job to one requiring much standing or walking. Besides the etiological factor of "being on one's feet continuously" other factors enter. The employee who is in a run down condition, who is convalescent from a recent illness, who is suffering from some other ailment, such as a chronic sinusitis, a gonorrhea, or a furunculosis, is more prone to develop a weak foot.

An expedient prophylactic measure is to prevent an employee who has just returned to work following a more or less protracted illness from being placed on a job requiring "being continuously on the feet." If it is not possible to place the workmen on a job requiring alternately a sedentary and ambulatory position, it is well to put him first on shorter hours, gradually increasing to full time. It is better for him to keep working, even at a reduced wage for a short time than to follow a course which may mean complete incapacity later on. A man with an infection who is in a "continuously on the feet" job should be cautioned to rest whenever possible.

Workers' shoes should receive especial attention. However, the physi-

cian is apt to find that all his logical reasonings sound a very feeble remonstrance compared to the clarion decree of style. The male worker needs to be cautioned as regards the wearing of oversize shoes or tennis sneakers. It was found expedient in the army to lay much stress on the shoes of the soldier. Might it not be well to devote a little more time to the feet of our industrial soldiery?

The symptomatology of weak foot is varied. In only a certain percentage are the pain and discomfort localized in the arch. In many instances not even pain or tenderness of the muscles of the legs or thighs are the outspoken symptoms. General lassitude, vague pains in the back, exhaustion towards the end of the day's work may be the direct symptoms of a weak foot, in such cases the diagnosis can only be made by the process of exclusion. Examination of the foot itself may show nothing. The character of the walk is more apt to be the earliest clue. The patient may walk "stiff footed." Some overcome the weakness in the foot by voluntarily throwing the weight on the outer side of the shoe, and walk pigeon-toed. This is a self-learned remedy and a good one. One should not, of course, attempt to correct a "pigeon-toed walk" acquired for the sake of resting the foot until the foot is really strengthened. A more common walk will be the walk with the foot rotated outward, the splay foot walk. Here the patient tries to overcome the effort of rising on the ball of his foot by pushing himself along much as one does on skates. A series of sprained ankles arouses suspicions of a weak foot. It is commonly known that the actual amount of flattening of the arch has but slight relation to the amount of physical discomfort. A slight tendency to evert the foot while standing, an outward curving of the Achilles tendon are early signs of a weakened foot.

A pronounced case of so-called second degree flat foot. The transverse arch is almost obliterated. The patient is in a typical walking attitude, the feet rotated outward.

It is commonly known that the actual amount of flattening of the arch has but slight relation to the amount of physical discomfort. A slight tendency to evert the foot while standing, an outward curving of the Achilles tendon are early signs of a weakened foot.

Corrective Measures Used

The urgent problem in such conditions is what to do to overcome the condition and still keep the worker on the payroll. Obviously, when the condition is the result of occupation, change of employment is initiated where possible. A man who has developed a weak foot from standing will often be relieved if the change is only to a walking job, though it may be necessary to reduce the working hours, or to shift the handicapped worker to a sedentary post. The im-

A boy convalescing from an acute infectious disease. He has weak feet and of his own accord has shifted his weight to the outer side of the feet, walking "pigeon-toed." To correct him of this method of walking would precipitate symptoms of "flat foot." As he becomes stronger he will spontaneously resume his former step.

provement of the patient's general physical condition is of prime importance. Here the social worker, provided the factory has a social service department, will be of the greatest aid to the industrial surgeon. The shoes should receive attention. Adhesive strapping should be tried as a temporary measure which will often do much to tide over the case until a betterment in the general physical condition will result in a spontaneous strengthening of the ankle. A simple strapping is more efficacious than a heavy complicated one. The foot should be strapped in a position of inversion, at right angle to the leg.

Exercises usually are relied upon, and justly so, to strengthen the muscular support of the ankle. However the average worker will not take kindly to a set of gymnastics. He must get up early as it is and will begrudge an extra five or ten minutes for the sake of uninteresting calisthenics. During the day he has no time for a set of exercises and at night he is too tired and in such a condition exercises do more harm than good. However, in spite of these facts, provided he can be made to see the importance of such a procedure the worker can be taught a few simple maneuvers which will exercise the muscles of support and which he

can carry out while at work. He is instructed to rise up on his toes now and then during the day. While at work, he can at intervals invert and straighten his foot. If he is standing, this means rising on the outer border of his foot. It is well to instruct him to walk "pigeon-toed" from time to time. This will not only tend to overcome the vicious habit of abducting the foot, but, by throwing the weight on the outer border, will also rest the foot.

The efficacy of "arch supports" to be put in the shoes is a moot question. Unscientific or not, in my experience arch supports have in many instances given great relief and, if so, the patient should be allowed to wear them. It should, however, be impressed upon the patient that the support is but a temporary measure, to be used in conjunction with other treatment and not to the exclusion of corrective exercises. The supports at first may be worn continuously. As soon as possible they should be worn only at intervals when the patient is tired, during periods of special stress, etc. It is well to use the arch supports in the evening when the patient returns from work. The habit of taking off the shoes and walking about the house in loose slippers, moccasins or stocking feet, is a bad one. The tired foot needs support. It is a natural desire to get out of the heavy working shoes as soon as possible. By bandaging the arch support to his foot and then putting on his slippers, the worker can best obtain rest.

A simple corrective exercise, easily employed, is achieved by standing on the toes now and then during the day.

Discomfort from weak feet may be relieved by throwing the weight on the outer border of the feet. A third exercise is a combination of the exercises shown, the patient standing on the toes, rolling back to the outside of the feet.

The question of shoes as I have said is an important one, and a difficult one for the industrial surgeon. A shoe which will not crowd the toes, which will be long enough, which will have a broad firm heel to support the weight, is apt to be not in "style." The decrees of fashion are not lightly put aside. Occasionally a worker will be found who can be induced to wear the proper shoes.

A shoe which even approaches the sensible type can be built up on the inner margin and this may be entirely sufficient to relieve the patient of all symptoms. The shoe worn by the average male worker is adapted to this modification. A shoe with a high French heel cannot be altered to cause inversion without greatly increasing its instability. Soaking in hot salt water, just before retiring will give great relief for aching feet.

Calluses on the sole of the foot are frequently concomitant symptoms of weak foot. Aiding the weak foot will in a large percentage of cases cure the calluses. A persistent metatarsalgia will often respond to the weak foot treatment. A plate with a support for the transverse arch is frequently indicated.

Emphasis should be laid on the fact that the building up of the general physical condition is the most important therapeutical procedure. It might be well to suggest in closing that a painful arch may often respond to treatment with a tonsil snare, a dentist's drill, or an urethral sound.

Industrial Nurses in New England

BY EVELYN L. COOLIDGE, R.N., PRESIDENT, NEW ENGLAND
INDUSTRIAL NURSES ASSOCIATION, BOSTON, MASS.

THE New England Industrial Nurses Association was organized in 1915 with eleven charter members, all of them graduate nurses employed in various factories and mercantile establishments in and around Boston, and was, as far as we know, the first such organization in existence. The meetings are held the second Saturday in each month from October to June, inclusive, at 7 p.m., at 3 Joy St., Boston, Mass. At first these meetings were held in the office of the Boston Tuberculosis Association, but this room was soon outgrown, and the use of the Town Room Library, in the same building, was given to the Association at a nominal rental. This room is still being used, but with the continued growth of the Association a larger hall will soon be necessary. The Association has grown rapidly and now numbers more than two hundred members, representing all the New England states, as well as New York, Tennessee, Colorado, and New Brunswick. The firms at a distance from Boston employing nurses who are members, invariably pay the traveling expenses of their nurses in order that they may attend the meetings frequently, as the employers realize the mutual benefit derived from attendance at these conferences.

The first hour of the meeting is devoted to the discussion of problems, often following ten-minute papers by members on various phases of their work. The second hour is given over to speakers of authority on subjects relating to industrial betterment, after which time is given for questions. Absent members send in questions which are discussed at the meetings, the result of the discussion being included in the full report of the meeting sent to all members each month.

Addresses have been made before the Association of Labor Laws, Workman's Compensation, State Health and Relief Agencies, Food and Bad Working Conditions (illustrated with slides), Vocational Rehabilitation of the Injured in Industry, Relation of the Medical Department to Industry, Nutrition in Industry, Organization of the Medical Department, Records, Value of Absentee Visiting, The Medical Department from the Workman's Viewpoint, Mental Hygiene in Industry, and many other subjects of interest and value to the industrial nurse.

The annual meeting is held the

second Saturday in January, at which time the officers for the ensuing year are elected. The present officers are as follows: President, Miss Evelyn L. Collidge, R.N., Lever Brothers Company, Cambridge, Mass.; first vice-president, Miss Elizabeth Whitty, R.N., Texas Company, Providence, R. I.; second vice-president, Miss Elizabeth Kob, R.N., Hockanum Mills, Rockville, Conn.; recording secretary, Mrs. Louise H. Munro, R.N., Holtzer Cabot Company, Roxbury, Mass.; corresponding secretary, Miss Henrietta G. Lawrence, R.N., Simplex Electric Heating Company, Cambridge, Mass.; treasurer, Miss Florence L. Berry, R.N., Florence Manufacturing Company, Florence, Mass.

The Association endeavors to maintain a high standard in the industrial nursing field. A nurse in good standing, who is a graduate of a recognized training school and who is employed by a corporation or by an individual in the interest of his employees, is eligible for membership. Associate members are graduates in good standing from a recognized training school who are doing part time factory work, or supervisors of such nurses. The honorary members at present include: Mrs. Anne M. Staebler, R.N., executive secretary, Massachusetts Health in Industry Committee, through whose interest and efforts the Association was organized, who is honorary president, having served two years as president; Florence S. Wright, R.N., deceased, author of "Industrial Nursing"; and Mrs. Austin T. Levy, lay member of the Industrial Section of the National Organization for Public Health Nursing. The Association has representation on the Board of Directors of the Industrial Section of the National Organization for Public Health Nursing.

The Association desires to bring before the general public, especially the employer of labor, the fact that the graduate nurse in industry, trained for that particular field of nursing, is a distinct economic asset, in that she not only cares for the sick and injured in the plant, thus keeping them on the job, but teaches them all, executives as well as employees, how to *keep* well. The nurse has a distinct function in fostering the spirit of cooperation in measures looking toward community health and, if her activities take her to the workers' homes, she may render a greatly broadened service.

Canada Reports an Industrial Fatigue

A recent report of the Committee on Industrial Fatigue of the Council for Scientific and Industrial Research of the Dominion of Canada is on General Conditions of Industrial Hygiene in Toronto. Seventy-six plants in Toronto were studied and the report includes a summary of conditions as to hours of work, medical service, sanitation, fatigue, occupational diseases and welfare. A large part of the report is taken up with a discussion of the time lost from sickness.

Eight benefit associations in Toronto were studied and their statistics and the lost time from sickness were tabulated for the year 1919. Charts and tables are presented which are extremely significant in view of the scarcity of accurate statistical material on this subject.

The Committee has presented the whole subject of industrial hygiene to the chief plants in Toronto and its plan for the future is to undertake "some specific piece of research from which definite conclusions can be drawn on some concrete problem however small."

Pleasing Health Propaganda

The most delightful piece of health propaganda published in recent years is the Health Mother Goose gotten out by the Metropolitan Life Insurance Company, written by Elizabeth E. Watson and illustrated by Emma Clark. Any child and any grown-up who love Mother Goose as all children and all grown-ups should, will find this newest Mother Goose a joy.

If all health propaganda could be as simple and straightforward in going to the heart of things, we should have a healthier, happier people. Mother Goose jingles should never be separated from their illustrations and Miss Clark's illustrations are as satisfactory and instructive as one could wish, but even without pictures, Miss Watson has succeeded in keeping the Mother Goose spirit.

There was a man in our town;
He was a Doctor Wise,
Who wanted folks to keep quite well
And so he did advise
Fresh air, good food, and lots of sleep
With merry times each day,
And all the folks who followed him
Were happy, well and gay.

Jack Sprat was strong and fat,
For he drank milk and cream;
Ate vegetables and lots of bread,
And left his plate quite clean.

The Routine Physical Examination of the Worker

Its Individual Value Depends on the Physician;
Its Public Health Value on the Management.

BY CHARLES K. ERVIN, M.D., CINCINNATI MILLING MACHINE COMPANY, CINCINNATI, O.

PHYSICAL examination of workers, although carried on by some plants as early as 1900, received its greatest impetus during the war. Necessary as it was before, its importance became emphasized, as great numbers of the physically fit were in the army, and industry had to use such labor as was then available. The physical examination at this time enabled the employment manager to place those physically handicapped at jobs they were capable of performing.

Some of the plants, which engaged in this work early, did so because of the interpretations placed upon workmen's compensation laws in certain states. Now, however, they realize the advantages to be gained in a new production program.

This subject divides itself into two heads, differentiating only as to the time: (1) Examination at time of employment; and (2) periodic physical examination. After all, there should be only one kind of physical examination, and that is a thorough and complete one, made with the utmost care and embracing everything from the top of the head to the sole of the foot.

Features of Examining Room

The examining room or rooms should be apart from the treatment rooms. Men like privacy and their wishes should be respected. Some intimate questions are asked; they disclose professional secrets, and the industrial physician will elicit only such answers as the degree of privacy affords,—just that much and no more.

The room should be well lighted, well ventilated, and, above all, should be free from noise. It should be equipped with all necessary instruments for nose, throat, ear, teeth, eye, and all special examinations, including x-ray apparatus. Either in this room or connected with it, there should be a well equipped laboratory.

It is not necessary that this room be set aside exclusively for physical examinations. It may be used every day for special examinations of eyes, ears, throat, chest, or heart.

When the author of this article had finished his internship in one of the large hospitals and was on the eve

of starting into general practice, a well known physician of this city offered this advice: "Make a thorough, complete, physical examination of every patient who comes into your office. This is the secret of becoming a good physician."

This advice, coming from one who had experienced years of success, seems worth following. It applies to the examination of the worker at any time, and particularly at the time of employment.

It requires time to do this, but any other kind of an examination is worthless. Don't try to beguile yourself or the management into the belief that it takes a physician to discern a missing arm or an eye and that in so doing you are better able to place the man. Any good employment manager could do the same.

It does, however, require a physician to detect a diseased eye, a chest condition, a heart lesion, a nephritis, a hernia, or any of the many diseases to which man is susceptible. These are the things you can only discern by the proper kind of an examination.

At railroad terminals a thorough inspection of the train is made. If one wheel is overlooked, it may be faulty and cause the fatal wreck. The same careful inspection should apply to the human element in industry.

Mental Attitude Counts

First impressions should always be good and there is no better opportunity for good psychology than at this first examination. It is the first contact the new man has with the firm. Your thoroughness, your care in handling him, privacy, and the taking of sufficient time to gather complete data, all make a lasting impression.

An examination can be made without undue exposure. Few men object to exposure to the waist line. A sheet or blanket can be used for the timid.

In the examination of the heart and lungs of women workers, clothing should be removed to the waist line and a sheet 3x5 feet, slit to the center, always used. This should be done by a lady attendant, if the physician doing the examining is not a woman.

Do not deceive yourself or try to

persuade the worker into the belief that you have examined his or her heart and lungs unless you have seen the chest in action. An eye well trained in the powers of observation will often reveal as much as the stethoscope.

To make a complete examination, it is best to have a certain method of routine, which will enable rapid procedure but assure that no detail is overlooked, and provides a record for future reference.

The following routine has been found the most successful for a general examination; special conditions, such as tuberculosis, or any condition involving the special senses, requiring a chart with more detail:

Age..... Weight.....
Weight one year ago, Best weight and when,

Height
Family History: Father, mother, sisters, brothers.

Previous Personal History: Occurrence of measles, flu, and time confined to house, pneum, rheumatism, colds, tonsillitis, grip, constipation, epilepsy, scarlet fever, tuberculosis. Previous injury, sickness due to industry.

Veneral History
Eyes: Visual acuity, right and left, both with and without glasses.

Ears: Condition of drum, right and left, history of discharge from ear. Hearing—watch test.

Nose: Septum, turbinates, obstruction.

Mouth: Tongue, condition of gums, pyorrhea. Speech—impediment.

Throat: Tonsils, pharynx.

Teeth. (This record should be on a numbered chart.)

8 7 6 5 4 3 2 1

Right 8 7 6 5 4 3 2 1

1 2 3 4 5 6 7 8

Left 1 2 3 4 5 6 7 8

Number missing, crowns, bridge, fillings, snags. It is only by the use of such a chart you can gain an idea of the masticating efficiency.

Thyroid (special attention).

Glands of the neck. While palpating these glands, examine for pediculosis without the knowledge of the applicant.

Heart. Position of apex in reference to mid-sternal line and intercostal space.

Lungs.

Chest: Development, expansion uniformity, etc.

Abdomen, liver, spleen, stomach, bowels, scars on abdominal wall, their condition and history.

Hernia: Inguinal, complete, incomplete, size of external ring. Special attention to impulse, femoral, ventral, umbilical, postoperative.

Hemorrhoids, fissures, fistula.

Genitals: (Varicocele, hydrocele, note size); scars, undescended testicle.

Skin: Eruptions, dryness, acne.

Limbs: Conformation, deformities, contractures, varicose veins, joint motility.

Hands: Deformities, motility.....

Spine deformities, motility.....

Nervous System: Tremors, knee reflex, Romberg and Babinski signs, seizures, evidence of scars on face or tongue.

Arteries: Condition of.....

Pulse: Standing and sitting; variability; regularity.

Blood Pressure. This should be taken in every case.

Urinalysis: Chemical in every case, microscopic where indicated. No examination is complete without it.

Psychological Tests

While talking with the applicant during the examination, the physician in industry, if he has properly trained himself, can secure a fair estimate of the man's mental condition. He can secure a fair idea of the applicant's general intelligence. He can detect mental defectives and can secure the man's mental attitude toward industry, number of previous positions held and attitude toward them, as well as the applicant's general outlook on life.

It has been my good fortune in the army to work in a team of examiners where we examined thousands of men, in which work scores of mental defectives, epileptics, morons, and numbers of those unfit, were picked out after a two minute examination.

Special examinations, such as a Wassermann, blood examination, and bacteriological tests should be made in special cases, either in the shop laboratory or referred to someone doing that specific work.

A physical examination conducted in this manner will enable the industrial physician to safeguard health and thus maintain efficiency at a maximum. It places him in a position (1) to exclude communicable diseases; (2) it enables him to place the physically handicapped; (3) to discover remedial defects which, when corrected, increase efficiency and prolong life; (4) to secure a complete history of the man's condition when beginning work. This is a very necessary thing in case a man later contends his work interferes with his health or that he is losing weight. Or it may clear his mind of a delusion when he can be shown that he is in as good

condition and in many cases better than when beginning work. In case a man has a single hernia and develops one on the other side, protection is afforded by the knowledge of the condition of the ring on the latter side at the time of employment. (5) It enables the exclusion of those who, because of some gross defect, are unfitted for employment. (6) From a humanitarian viewpoint it thereby becomes possible to place those needing medical attention, whether disqualified or hired, in the hands of the best physicians, the best hospitals, and the best sanatoriums.

Periodic Physical Examination

In considering the dangerous processes to which workers are exposed in many industries, the periodic physical examination becomes as important as the examination at the time of employment. Occupational diseases are receiving more attention now than ever before and it is only by this frequent examination that we will be able to locate the department in which they occur and institute proper preventive measures. Other advantages are: (1) It affords the means of following up those with known disability. (2) The requirement of frequent examinations is a safeguard where there is handling of food. (3) Comparison can be made of the physical status of the employees from time to time, with the object of increasing the health standard of the entire force. (4) Employees returning after an illness have the advantage of receiving a physical examination. (5) Safety is promoted by periodic examination of everyone where a known health hazard exists. (6) In the event of placing at work an applicant whose health status is somewhat uncertain, frequent examination furnishes the necessary follow-up. (7) All executives and office employees need the frequent examination more often than the workmen. They lead a sedentary life. It is on the executives that responsibility rests. They are hard to replace and if sickness comes, the loss to the firm is multiplied several times, and here the value of periodic physical examination proves its value.

After completion of the examination, unless records are convenient and readily available, the efforts of the physician are partly wasted. This record can readily be kept on a 5x8 card or on a double card, using four sides.

The physical examination records should be filed separate from other papers and should be in the treatment rooms, readily available when the em-

ployee presents himself at the clinic for minor ailments. The records should be indexed according to department and cross-indexed as to occupations, age groups, and according to defects detected. In the file, at the beginning of each group or department, should be a description of the department, the location, the kind of work, sitting or standing, or heavy lifting. It should be complete and concise enough to give the physician a good conception of the kind of work the employee is to do.

An ideal system for handling physical examination records can be worked out with one of the standard visible card systems which reveal by one glance at the record a mental picture of the physical condition of the entire department. By means of different signals, the more pronounced physical defects or diseases that have been found can be brought out.

With these histories conveniently at hand, they will receive attention more often than when in a folder with numerous other cards and all placed in another room.

Standardization and efficiency is stressed in all our manufacturing output, yet usually the methods of keeping physicians' records are most crude.

It is to be remembered that in making a physical examination the industrial physician serves the employees and in serving them well renders the management the highest degree of service.

If physical examinations are conducted with the needs of the employee ever in mind, there can be no objection to them on the part of the men. The greatest cause for complaint in the past has been because of the great number of rejections, which have been as high as 10 and 15 per cent in some cases. In a recent report, it is encouraging to note that the average proportion of rejections is only 2.8 per cent. It also shows that of those accepted for employment, 30.3 per cent were substandard. One firm reporting gives the rejections as low as one-half of 1 per cent. Our own rejections were 1½ per cent. This record shows that the handicapped are being placed and that probably the only time there is a rejection is when the man would become a danger to himself, to others, or to property.

(1) Anything but a complete and careful physical examination is a useless waste of time and energy. This idea should be thoroughly sold to the management.

(2) Proper filing of the record is

called for so that the physical findings are readily available to the physician when the employee presents himself in the clinic for minor ailments. This will always give the physician a proper background in his subsequent examinations of the patient when presenting his complaints, offering the opportunity also of making notations on the original card as to variation in weight, in physical well being, etc.

(3) The use of former records of this type before prescribing will impress the employee with the thoroughness and the intelligence of the method and the worthwhileness of the original examination.

(4) Few examiners realize that the reaction of the patient to the examination and the type of answers that he gives, is perhaps the most valuable index that the employer can pos-

sibly get as to the desirability of the applicant for the job. The physician should so train himself that the employee's reaction to a good physical examination will largely take the place of specific mental tests, which are, in the main, impracticable as applied to industrial workers at large.

(5) A true test as to whether the physician is holding his own with the employees and with the employer is indicated by the attitude of the executives toward having physical examinations made of themselves. The employer and the industrial physician should more thoroughly appreciate that in no better way can the company dignify the service offered by the Medical Department than by having the employees see that the executives so value the medical service that they themselves may use it, and thus give it the stamp of approval.

from industrial medicine? They were committed to the insurance system for weal or for woe. Medical examination of the employees by the firm's doctors was not feasible but might be done by state doctors, as under the panel system. In the United States they had no insurance system to retard the spread of industrial medicine.

Dr. E. E. Mather stated that he and a woman doctor worked "whole time" for the Messrs. Cadbury. There were about nine thousand employees, one thousand being under sixteen. They treated all who came for treatment,—men, women, and children,—and had no difficulty with the panel doctors. They had a dental clinic and the firm paid for special cases to be sent to hospitals and consultants. The medical examination of existing employees was optional, but the examination of applicants was compulsory.

At the afternoon session Dr. E. L. Collis, professor of preventive medicine at the University of Cardiff, spoke on "Health Problems in Industry" and said in part that he was convinced there was a very close connection between industrial unrest and the public health. If the nation was sound, the nation would think soundly. The medical profession had in its hands the foundation and the basis of the whole structure of civilization. It was not enough for the doctor to wait until the individual in the factory was ill; he should see what could be done to prevent illness.

Cost of Adequate Service

What was going to be the cost and value of an adequate medical service to industry? It was demonstrable that labor turnover cost the country \$500,000,000 a year; but labor turnover could be reduced 70 per cent by medical supervision—which meant a saving of \$350,000,000. Add to this the saving that could be effected on lost time and convalescence, and the medical profession could offer industry \$750,000,000 a year. Even if half of the forty thousand doctors in the country were paid \$10,000 a year each by industry, there would still be a saving of over \$500,000,000.

Dr. W. W. Renton, who had worked for the firm of Vickers, said that this firm had a hospital and special clinics for electro-therapeutics, massage, etc., and that insurance companies sent patients for treatment. Dr. D. A. Coles acted as "works doctor" for the Gas Light and Coke Company. He was not on the panel himself and had no trouble with the panel practitioners. Mr. Seeböhm Rowntree, cocoa and chocolate manufacturer, said that the

British Industrial Medicine

BY OUR LONDON CORRESPONDENT

AS PRESIDENT of the Industrial Welfare Society, the Duke of York opened on June 2, last, a conference of medical practitioners engaged in industrial work, at the headquarters of the Society at 51 Palace Street, Westminster, London. Dr. R. M. Wilson introduced a discussion on "Medical Service Industry" and said that every big employer who had done any good in the world knew that there was never any profit in underpaying workmen. The healthier the workman and the better his surroundings; the more cheerful he was, and the greater would be his actual output; and, if the employer had listened to the factory inspectors and doctors, the trouble between labor and capital would have been healed years ago. If medical men showed employers and employees that a particular thing, such as bad industrial conditions, was against the interests of both, they would remove the basis of their quarrel and raise disputes to another level. The fundamental doctrine of industrial medicine was that there was no disparity of interest between employer and employee. What helped the one was bound to help the other. Doctors were not tradesmen, they were not there merely to make money, a fact which gave them an enormous advantage. Sir Ronald Ross, for instance, who had made many millions for the capitalists, who had opened the door of the East to the British Empire, and who had made

malarial countries habitable to the white man, has received nothing, relatively speaking. Yet he, the speaker, would not change the position of Ronald Ross for one of the capitalists who had made fortunes. The medical profession should have a preventive outlook and adopt the "Mackenzie line of thought." Actual disease was an evil process and we must study the processes which led up to it. For successful factory work in medicine they must have a general practitioner who went right down to the humanity of the men or women. Specialists who might be inclined to look at their patients as No. 1, No. 2, and so on, would never be of much good to the British public.

Welfare Based on Medicine

Dr. I. M. Legge, of the House office, laid stress on the point that all industrial welfare must be based on medicine. The movement for industrial "doctors" was only in its infancy. He would like to put some questions to the meeting. What was the relation of "the works doctor" to the panel doctor, to the edifying factory surgeon, to the welfare superintendent, and to the Whitley Councils? Could they have a panel of works doctors, or could part time industrial work be linked up with the panel system? Were there clinics established in the works, ophthalmic, dental, etc.? Could they show to the employer results in pounds, shillings, and pence

firm had fifteen years experience of medical work in industry, and there was no question as to its value. What was wanted was an educational campaign among employees to prove to them that under existing figures a medical service paid. But the cost was extremely small in relation to the wages bill. His own firm had spent \$10,000 a year, with a wages bill of \$6,250,000. There was no capital outlay required—only three or four hundred pounds for a small consulting room and a few appliances. Dr. Cree of Messrs. Swan & Hunter, the Newcastle shipbuilders, said he encouraged men to come to the ambulance room for the smallest injuries, and as a result sepsis—which was formerly very common owing to the dirty nature of the work—had been eliminated entirely. This represented a great saving. Sir Thomas Oliver, M.D., pointed out as a pounds, shillings, and pence gain that the match industry was now free from jaw and dental trouble. He thought there

should be a state department for industrial medicine as in France and in the United States. As showing the interest now being taken in industrial medicine in Great Britain at the present time, in the *Lancet* of June 11, a leading article was devoted to the subject. In this article emphasis is placed upon the fact that industrial medicine must not be made into another "close" specialism and it is obvious that if the general practitioner is to acquire a preventive outlook, he must have the opportunity for studying the effect on his patient of both home and occupational conditions. In order to insure the maximum of good health among workers, home, factory, and workshop conditions must be of a high sanitary and hygienic order. By promoting this object much ill-health will be prevented and efficiency increased. Naturally, prosperity and comfort will follow. Industrial medicine has a great future, and it the most essential factor in the prevention of disease.

Respiration and Physical Fitness

NOWHERE has physiological knowledge been placed to better practical uses than with regard to the principles of respiration. A study of the absorption of gases by the blood has made caisson disease a curable malady and has furnished the fundamental principles upon which the construction of mine rescue apparatus is based.

Formerly in the event of mine accidents, volunteers were always ready to risk their lives in the attempt to rescue men imprisoned in the poisoned atmosphere of the shafts, and many needless sacrifices of life were thus made. Now it is realized that no one should attempt such rescue work unless he is physically fit, and unless he is properly protected with apparatus against the poisonous atmosphere he must enter.

In the Second Report of the Mines Rescue Apparatus Committee, Department of Scientific and Industrial Research (England), 1920, is to be found a remarkable summary of the processes of respiration. The way in which the pressure of carbon dioxide in the blood acts independently of the oxygen pressure is emphasized, and attention is drawn to the different and independent action of oxygen-want and carbon dioxide excess in stimulating respiration.

In analyzing the Report, the *Lancet* quotes evidence (1) to show that while in an ordinary person diffusion

of gases through the pulmonary epithelium will explain the access of oxygen to the blood, "the physical laws of diffusion do not explain the phenomena of blood-oxygenation when the subject is making a special demand on the oxygen supply," either because he is doing physical work or because, as airman or mountaineer, he is breathing rarified air; and (2)

Rear View Paul Apparatus. The air the man breathes is carried with him.

in support of "the view that the epithelium is not a mere porous diaphragm, but that living cells of which it is possessed have the faculty—which they exercise at need—of secreting oxygen from the air and of handing it forward at enhanced pressure to the blood."

Men in good physical training, such as practical miners, were found to possess this power of secreting oxygen from the air.

Hence, in men who are accustomed to muscular exertion, there is no deficiency of oxygen in the arterial blood when ordinary air is breathed until exertion is pushed to the utmost. For this reason they also receive no benefit from breathing air enriched with oxygen. On the other hand, in men who are not accustomed to muscular exertion, the epithelium fails to pass in the proper supply of oxygen unless the diffusion pressure of oxygen is raised in the alveolar air by the enriched inspired air. Hence these persons benefit by enrichment of the air with oxygen. . . . It is evident that the physiological response of a man to oxygen during muscular exertion furnishes an interesting test of whether or not he is in good training as regards his lungs. Physiological fitness depends not only on the lungs, but also on ready adaptation of the circulation, muscles, nervous system, etc., to whatever exertions are required. . . . In ordinary cases, however, lung fitness is an accompaniment of general physical fitness, and may therefore be taken as a measure of it.

It may be inferred from this that the method of testing physical fitness of airmen devised by Dr. J. S. Haldane should also be applicable to members of a mine rescue brigade, or to the capacity of athletes to endure the strain of strenuous and prolonged

The stringent requirements of rescue apparatus are based on physiological principles. Proto Fleuss apparatus.

exertion in contests. The thought further suggests itself that by the same means might be determined the most economical speed possible per liter of oxygen or per pound of food. The investigation revealed that when carrying a load of forty-three pounds—the weight of a rescue apparatus—the most economical speed for certain subjects was three miles for some subjects and four miles for others. Further valuable results are to be expected from research in the same direction. Protection for the safety squad and perfect adaptation of apparatus should grow out of these studies.

Effective protection is afforded by the apparatus which carries in one cylinder a supply of oxygen, and in the other caustic potash which absorbs the carbon dioxide exhaled.

Dr. Lanza Goes to Australia

The newly constituted Board of Health of Australia will undertake research along lines having to do especially with hygiene in industry preliminary to the enactment of health measures of far reaching influence. It is interesting to note that an American physician has been selected to head the Hygiene Section, in Dr. Anthony J. Lanza, who has been with the Hydraulic Pressed Steel Company, Cleveland, O., for the two years just passed. Dr. Lanza is by education and experience fitted for the important post he has undertaken to fill, having had immediate experience in industrial plants, and having been in charge of the Office of Industrial Hygiene and Medicine of the United States Public Health Service in Pittsburgh for some years. He sailed July 9, to assume charge of important new investigations.

Dr. Anthony J. Lanza appointed on Australian Board of Health.

Recent Compensation Decisions

FRANCO et al. vs. Seas Shipping Corporation, Inc., which was decided by the Federal District Court of Nebraska, April 15, 1921, interprets Congressional Act of December 26, 1920, providing that alien seamen found to be afflicted with certain diseases shall be placed in a hospital, the expenses involved to be borne by the ship owner and not to be deducted from the seamen's wages. The Court held that this Act is not limited to passenger vessels and that while without explanation it may seem unfair to impose on ship owners the duty of paying hospital bills to cure seamen of diseases due to their own vices, the Court will not substitute its own judgment for that of Congress. The case arose in admiralty where alien seamen employed on crew of an American steam freighter on arrival in the United States were found to be suffering from venereal diseases. They were ordered to a hospital and treated under the Act of December 26, 1920. On discharge they demanded full wages, the ship insisting on the right to deduct the amount of the hospital bills, its contention being overruled.—272 Fed. 542.

THE following cases interpreting the workmen's compensation laws of the various states turn upon or involve upon some medical problem or some question of physical conditions as opposed to the ordinary problem of statutory interpretation or

legal analysis. There is involved here possibly a question of the determination of the fact of physical disability based upon medical evidence or opinion and very frequently there will be holdings on either side, both pro and con in the different jurisdictions showing in a way the lack of standardization, the state of indecision concerning the judicial determination of medical problem, if such a term can be used.

The case of Strong vs. Sonken-Galamba Iron & Metal Co. was decided by the Superior Court of Kansas May 7, 1921, where an injured employee refused to submit to an operation for a hernia. It was held that the unreasonable refusal of an injured employee to permit a surgical operation where the danger to life from the operation would be very small and the probabilities of a permanent cure very large, justifies the Court in refusing compensation under the Compensation Law from and after the trial. The unreasonableness of this refusal is a question of fact to be determined from the evidence.—198 Pac. 82.

AN INTERPRETATION of the Oklahoma Workmen's Compensation law held that the law was for the benefit of the injured employee to provide for him proper medical and surgical treatment at the expense of the employer, in addition to the compensation provided for in the Act, which results from injuries arising in the course of employment.

The State Industrial Board is without jurisdiction to order the injured employee to submit to a major operation involving a risk of life, no matter how slight, in order that the pecuniary obligations created by law in his favor against his employer may be minimized. An award of the State Industrial Commission in case of injury resulting in hernia which required the claimant to undergo an operation or forfeit his right to compensation was held to be in error. The rule stated is that the Industrial Commission must award compensation for the disability of an injured employee as it exists at the time of making the award, and the Commission is without jurisdiction to impose upon such injured employee the option of submitting to a major operation or forfeiting his right to compensation.—*Hentley v. Oklahoma Union Railway Co. (Okla. 1921) 197 Pac. 488.*

DOUGHERTY'S case decided by Supreme Judicial Court of Massachusetts, May 25, 1921, holds that a sunstroke suffered by an employee while doing the work he was employed to perform, was received in the "course of his employment." Within the workmen's compensation act an injury "arises out of employment" within the meaning of the Act when it appears in view of all the circumstances that there is a casual connection between the conditions under which the work is required to be performed and the resulting injury. In a proceeding under the workmen's compensation act for the death of an employee who suffered a sunstroke while delivering a load of coal, where there was no evidence that when engaged in delivering the coal he was peculiarly exposed to the danger of sunstroke by reason of the nature of the work, the finding that the claimant had not satisfied the burden of proving that the employee by reason of his employment was subjected to materially greater danger than other outdoor workers was not unsupported by evidence as a matter of law. The decree of the Commission was affirmed.—*131 N. E. 167.*

CARROL vs. Industrial Commission of Colorado, 195 Pac. 1097, recently decided by the Supreme Court of Colorado, holding that where an employee had organic heart trouble and the strenuous work of pitching alfalfa hay in an enclosed building, combined with breathing dust-laden air, brought on an attack of heart trouble causing instant death, the condition of the air, or the fact

that it was dust-laden, was proximate cause of the death. This death was a result unexpected and unintended, and therefore an "accident," and death resulted from the injury proximately caused by accident within the Workmen's Compensation Act.—*195 Pac. 1097.*

JACKSON vs. Industrial Accident Commission of California. The disabilities of a servant due to his general physical condition and not traceable to the injury, are not compensable under the Workmen's Compensation Act.—*195 Pac. 719.*

THE Minnesota Supreme Court recently held that the Workmen's Compensation Act in force in 1917 did not give to the physician or surgeon who furnished medical treatment to an injured employee a right of action for the value of his services against an employer who had not requested or consented to the furnishing of the treatment given. In no event can an employer be held liable for such treatment in the absence of a finding that he either consented thereto, refused, or was unable to furnish needed treatment.—*Beach & Gendler (Minnesota, 1921) 182 N. W. 607.*

IN THE case of the Gatloff Coal Co. vs. Ramseur's Adm'x, the Supreme Court of Kentucky, in an action for the death of a coal miner by gas poisoning, alleged to be due to insufficient ventilation, held that the evidence was sufficient to authorize the submission to the jury of the issue whether the breathing of poisonous gases was a direct and proximate cause of his death.—*228 S. W. 1028.*

A CASE recently reported from Maine holds that the bursting of a blood vessel from the increased blood pressure resulting from the exertion of an employee in lifting a sack is an "accident" within the Workmen's Compensation Act, the term "accident" being defined as an undesigned and unexpected event.—*Patrick vs. J. B. Ham Co., 111 A. 912 (Me.)*

THE question of compensation for industrial injury receives a somewhat different interpretation in a recent Pennsylvania case. It was found, in a proceeding under the compensation act to obtain compensation for the death of a servant, that the Decedent, while in the performance of his duties, met with an acci-

dent in attempting to lift a brake stick, and thereby suffered such strain internally as to cause hemorrhage of the stomach and bowels. His death followed and the court held that the evidence sustained the finding that his death followed as a natural consequence of this injury.—*Zukowsky vs. Philadelphia and Reading Coal & Iron Company. (Supreme Court of Pennsylvania, 1921), 113 A. 62.*

Training in Rehabilitation Work

Training courses in the rehabilitation of physically handicapped persons now appear in the catalogues of two universities. The course being given at Harvard University, in the Bureau of Vocational Guidance, is described as follows:

Rehabilitation and Reeducation of Handicapped Persons.—Discussions of occupational therapy, vocational guidance, try-out courses, testing, training, placement, and employment supervision, with an examination of present practices, social and economic needs, and desirable developments.

At the University of Chicago a course given in the graduate school of Social Service Administration is described as follows:

Physically Handicapped Persons.—The course includes study of types of handicapping disabilities and their causes and treatment, as related to the functioning of medical agencies; the effects of physical disability on earning capacity, and its relation to the processes of family rehabilitation; opportunities for disabled persons in industry and the use of job analyses in employing them; vocational training and labor placement; the value of personality in overcoming handicap, and of the community attitude in the work of rehabilitation; physical defects among school children in relation to handicaps in adult life; the safety movement and other methods of prevention; state and national legislation for the rehabilitation of physically handicapped persons. Useful especially to students of industrial management, teachers of vocational subjects and those interested in family case-work or hospital social service.

Child Hygiene in Tennessee

A course of twelve lectures on hygiene and sanitation is being planned by the Nashville Commercial Club, with the assistance of the Rotary and other clubs of the city. The lectures will occur on a month during the coming year and will be given by prominent Nashville physicians. The first lecture was scheduled for June, the subject being "Nashville Babies." The July lecture, given by the city health officer, was on "Nashville School Children," according to the *Nashville Banner* of June 5.

The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents

Sensible Aid for the Blind at Chicago Lighthouse

By EDITH L. SWIFT, EXECUTIVE DIRECTOR, CHICAGO, ILLINOIS.

A SIGHTLESS student at the Chicago Lighthouse when asked if he was totally blind made this reply, "No, sir, not totally, only physically." This attitude of blind people toward their handicap is the normal reaction to the treatment they receive at the industrial training school for the adult blind which is conducted by the Improvement Association for Blind People at 3323 West Twenty-second Street, Chicago.

Chicago was among the first cities in this country to recognize the right of normal blind people to a vocational training which would enable them to be self-supporting members of the community. Nine per cent of Chicago's blind citizens have been trained to take their places in the fields of industry by the Chicago Lighthouse in the last twenty months.

The industrial training of the blind to fit them for work in factories and offices was begun by the Improvement Association for Blind People at the Chicago Lighthouse work shops in June, 1919. The school is maintained by private initiative and voluntary subscriptions and is the only industrial training school for the adult blind in Illinois. The Chicago Lighthouse is endorsed by the subscriptions investigating committee of the Chicago Association of Commerce.

The method employed is to study the individual blind men and women who apply for training. When something is found which they are able to do, they are given special training along the line of this latent ability. Confidence is gained by the blind student as the factory instructor works with him and gradually his self-reliance is built up. Through the courtesy and cooperation of employers openings have been found for stu-

dents of the school in various types of factory work and the teaching is completed in the factory at the identical operation on which the man is to be employed. The factory is first visited by the instructor and the foreman, under whom the blind man is to work, is convinced that the employment of a blind operative does not

This sightless man is a self-respecting citizen whom special training has enabled to earn his living by assembling contact points for the Edison Appliance Company.

mean that this man will be a drag on the production in his department. Often it is necessary for the instructor to have himself blindfolded and then do the necessary operations to win over the foreman to the idea that a blind man can do the work required of workmen who can see. The instructor keeps in touch through occasional visits, and, when need for additional instruction develops, he is able to continue the training so that the blind employee may not be limited to a single type of work.

The Chicago Lighthouse work shops are provided with materials on which to work by friendly firms who have become interested in this experiment in helping the blind to help themselves. In the reed shop one finds go-carts, baskets, and chairs in process of manufacture. Hand looms are in operation in the weaving shop where blind men and women weave beautiful textiles. The weavers memorize the patterns or write them in Braille and, once the choice of design and coloring is determined by the instructor, the weaver works independently with only occasional supervision. The textiles produced are sold in shops such as the Artists' Guild and the Service League for the Handicapped or direct to interior decorators. The mechanical operations taught in the school are varied. Such operations include the assembling of piece parts for phonograph motors, the assembling of automobile headlight deflectors, the threading of bolts, the operating of punch presses; in fact, any operation which makes it possible to train the fingers to do the work of eyes. Blind persons who are normal may be trained to do countless operations of a mechanical nature with speed and accuracy.

Blindness is considered a 30 per cent handicap, not a total disability. The men and women trained at the Chicago Lighthouse are taught to think of their handicap as something to be overcome not as an affliction for which they are to be pitied. Most of the students are mentally depressed when they apply for training, but a change is noticed after a few weeks. The blind respond very readily to intelligent guidance and cooperation and eagerly seek the training which

This man earns his way assembling automobile headlight deflectors at Mohr, Inc. Self-reliance does not suffer when real work becomes possible to the visually handicapped.

is to make them able to enter the field of wage earners.

Seventy-five thousand blind people are citizens of the United States and, according to the census, less than one-third of this number earn more than three hundred dollars a year. The greatest advancement along the lines of sensible aid for the blind has been made in the last two years by the organizations like the Chicago Lighthouse which have specialized in increasing the number of occupations in which the blind may find gainful employment. Normal blind persons do not seek charity but they need training and to be separated in the eyes of the public from the class of blind persons who are subnormal or have some affliction in addition to their sightlessness. Graduate students of the Chicago Lighthouse earn from twelve to thirty-two dollars a week. Of the two thousand blind persons in Chicago 189 have been made self-supporting through the vocational training given during the past twenty months at the Chicago Lighthouse. The average cost of training and placement is two hundred dollars. Persons who know that blindness for them is inevitable should go to this school early and prepare themselves for a trade or profession while some portion of their sight remains. The ability to distinguish light from darkness or to see an object as a blurred outline is of inestimable value as compared with total blindness. Even a little sight may be conserved, but it will atrophy if it is not used in many cases. The person whose sight is failing should be put where his surroundings are cheerful and his condition is understood. The knowledge that he is preparing himself for an occupa-

tion which will insure his independence when blindness comes will in some degree mitigate the dread of impenetrable darkness.

The world war has taught the public that blind soldiers and sailors can be rehabilitated and replaced in industrial fields. These soldiers of ours of whom there were less than three hundred have been given every opportunity to prepare themselves for wage earning by the vocational training given at Evergreen near Baltimore under government supervision. Their sacrifice will not have been in vain if the successful outcome of the government's work in training them brings to the consciousness of the American people the pitiable condition of the civilian blind. America owes her blind citizens training for service to America that they may become an asset, not remain a liability.

The Chicago Lighthouse has trained

blind people to be self-supporting in the following operations in factories:

Assembling: Automatic telephone piece parts, phonograph motor piece parts, electric light sockets, electric switches, hermetic sealing caps, paper cartons, gasoline lamps piece parts, nuts for gasoline lamps, headlight deflectors, ball bearing rollers.

Wrapping: Electric flat irons, furniture for shipment, dowels.

Sorting: Needles, trimmings from gaskets, rubber scraps.

Stacking: Laminations, mica.

Folding: Paper cartons, towels.

Mechanical Operations: Riveting press, operating foot punch press, nutting bolts on power machine, tapping, machine operation on power press, drill press operation on power press, threading ball sockets for motors.

Piano tuning, chair caning, fiber furniture weaving.

The blind also excel as basket weavers, baby carriage weavers, textile weavers, typists, dictaphone operators, and stenographers. Graduate students have earned \$30,000 in the past year at these occupations.

In cooperation with Peter J. Peel the Chicago Lighthouse conducted the first blind massage class in America and graduated eight competent masseurs. Two of these graduates were employed to work on the wounded at Fort Sheridan Hospital.

On the Board of Advisors of the Chicago Lighthouse which is conducted by the Improvement Association for Blind People are W. A. Alexander, Joseph M. Cudahy, Charles W. Folds, Dennis F. Kelly, Charles G. King, Alfred T. Martin, Joseph E. Otis, Peter J. Peel, Frederick H. Rawson, and Charles H. Thorne.

Chicago Lighthouse graduates are here employed by the Garret Go-Cart Company in the process of weaving baby carriage bodies.

Educational Needs of the Crippled Child

Mental Handicap Will Augment Physical Defect if Orthopedic Hospitals Are Not also Educational

By ALEXANDER E. HORWITZ, A.M., M.D., ST. LOUIS UNIVERSITY, ST. LOUIS, MO.

AT THIS age of conservation of human resources an opportunity is offered to redeem ourselves from our long apathy toward the crippled child. A strong liability can easily be converted into as strong an asset. We have never willfully neglected the crippled child; we have cared for him according to our lights, but these lights have changed and, in the view of modern standards of efficiency, the benefits conferred by us upon the children of yesterday are to be regarded as criminal today.

The physical care of the child is no longer the chief requisite. We have not accomplished our duty when we rest there. It is not to be denied that a sound body is the prime requisite for a sound mind, and to strive for that goal is laudable; but we must be alert to the fact that these crippled children will remain crippled, and to neglect the mental faculties while the physical condition is being improved is false logic and an irreparable wrong.

Unpreparedness for Life

The cripple is no longer regarded as accursed of God. He is to be regarded as the product of environment, our own creation. He is no longer assigned to Spartan mercies, although that was far more humane than our modern neglect. We save the child from an early innocent death, preserve and strengthen his body in so far as is possible under expert care, and thrust him unprepared upon a hostile, competing world. His handicap is doubled; a weak physique, an undeveloped mind. He is early thrown to the surface of the whirlpool, regarded as waste, and cast aside. He becomes an object of pity, repugnance, and charity—three conditions detrimental and fatal to mental development.

In the early formative period the crippled child's mind is capable of high development, higher in some degree than that of the physically sound child. His energies, deprived of the channels in which those of the normal child run, may be directed by proper guidance toward mental development. Given no guidance, or improper direction, he becomes introspective and

morbid. Morbidity is not conducive to the production of good citizenry. Unearned favors, euphoniously and erroneously called charity, are likewise not conducive to the development of a mind tending to self-respect. He who could easily have become a producer is become merely a consumer, a drain upon the community, and a drag upon himself. He performs no useful communal or social function. He hates himself; he hates his Creator, his environment. He is a king bee, its useful functions having been performed.

Schools Help Small Number

The number of crippled children is yearly increasing throughout the Union, despite our boasts of more ad-

this condition. There are state and private institutions where remedial attempts are made; in some, attempts, in others, realizations. The total number reached is but a fractional part of the problem. The establishment of public institutions in every state will prove an economy rather than an expense. Public opinion should be moulded and directed toward this economy. It is due the crippled child; it is not a favor. We create him, we should give him the means of livelihood. We maintain costly educational institutions for the normal child, and entirely neglect a large part of our school-age population. That he is physically unable voluntarily to attend school does not prove that training should be withheld from him. Educational facilities should be brought to him or arrangements made for group instruction.

For the treatment of crippled children there are at present four state institutions with a capacity of 685 beds: (1) the Massachusetts Hospital School, 300 beds; (2) the Minnesota State Hospital for Crippled and Deformed Children, 160 beds; (3) the Nebraska Orthopedic Hospital, 100 beds; (4) the New York State Hospital for Crippled Children, 125 beds.

Hospitals Conduct Schools

(1) The ideal is presented by the Massachusetts Hospital School in which the educational training is at a par with the physical care. Cooking, sewing, gardening, and shop work make proficient and self-sustaining individuals upon reaching maturity. The expense for the year amounted to \$93,125, a per capita per week of \$6.56, of which amount about half is appropriated by the state and the remainder obtained from other sources.

(2) The Minnesota State Hospital, according to its last published report (1916), cares for 160 children, where all modern methods in instruction and shop work are carried on. No mention is made of per capita cost.

(3) Nebraska Orthopedic Hospital gives modern instruction both in classrooms and wards. Only a small amount of shop work has thus far been instituted.

(4) New York State Hospital pro-

N. O. P. H. N.
Children like this are the wards of society. Fed on patent foods, and little of anything with regularity, this six-year-old child did not walk till she was five. Her restoration and education must go hand in hand.

vanced hygienic conditions. A true census is lacking; but the estimate, not exaggerated, is that of one per 1,000 of population, or 62,500 for all states, a vast army of inefficients for the creation of which we are responsible.

Let us not be too harsh upon ourselves in this matter, as there are bright spots here and there where intelligent work is conducted to remedy

Society's new sense of responsibility toward crippled children is typified by this scene from Spaulding School, Chicago, showing the physical director with her young charges.

vides scholastic instruction and useful arts.

In these four institutions scholastic and shop instruction in varying degrees is given in all. In one, gardening is taught. The expense to the taxpayers has justified itself. The average per capita of \$6.50 a week is moderate. The results obtained are satisfactory. Useful citizens are sent forth to compete in a free field. They are prepared for economic independence upon reaching maturity.

As a nucleus these institutions are serving splendid objects. The total number of children reached is less than 700 for the four states, or an average of about 170 for each state. Any one of our large cities could furnish this full quota of 700. The work should be broadened to include every crippled child of sound mentality. A concerted movement should be inaugurated toward the establishment of such institutions in all states. It should not be left to private initiative.

There are fifteen homes with a capacity of 763 beds. Of these one is educational.

There are eighteen orthopedic hospitals devoting themselves exclusively to crippled children. Of these two are educational. The number of beds total 1,200.

There are eight educational institutions for the crippled child, of which four have already been included under other heads. These eight institutions care for 600 children. The total of those cared for is 3,548. The total estimated number of crippled children throughout the country is 50,000 to 60,000. About 7 per cent of all crippled children receive care, either

physical or scholastic. A supplementary list is printed herewith giving the names, location, and the number of beds of the institutions serving the crippled child.

That all these hospitals, homes and schools care for but part of the crippled population needs no discussion. That an infinitesimal part receive educational training is another undisputed fact. That the child, where it does receive hospital care, should be neglected from an educational standpoint is a condition which should not be suffered to exist. That this child should be deprived of two or three years schooling, or, if older, of trade instruction, is not just to him or to the community.

The question arises as to where to place the responsibility for this educational work. It is an axiom in civic improvement that no innovation is adopted until it has shown itself practical under private experiment. The six private educational institutions and two state educational institutions where this work has been carried on for years are beyond the experimental stage. Definite results have been accomplished. It should be extended. It should not be left to private undertakings. It is a public problem and should be so regarded.

In each civic or state community a sufficient number of crippled children exist. These have as much a claim upon the community from an educational standpoint as the physically sound, and should not be disregarded. From a humane standpoint they deserve it. From a civic standpoint, they are children of taxpayers and should receive their share.

The city of Chicago is a pioneer in caring for its crippled children. Three hundred are here given special instruction at the Spaulding School, which gives a more varied course in shop and other work than is offered at any of the state institutions. The results are gratifying. The per capita cost is only slightly more than that of educating the subnormal child. Quoting from its bulletin: "The justification of the great per capita cost is not eight years of being different from his schoolmates, reeling 'I can't play as he plays,' 'I can't follow the same course of study, I am older than my classmates,' but 'I can.' Instead of being shielded and guarded or neglected by healthy, normal children, he helps and guards one weaker. Instead of brooding over his deformity, always under a wrong subjective influence, in the years when his disposition is in the making, his deformity is openly discussed, its possibilities and limitations laid bare. He even learns to laugh with his playmates at himself or them in their awkward attempts at adjustment. When they go into the world they return and discuss philosophically and without pain readjustments there."

Assuming that the responsibility is placed upon the city government, several problems present themselves. Is it advisable and desirable that the crippled child be segregated? More systematic work can be done where they are grouped. It also puts the child in better mental attitude. He sees children whose condition is worse than his own and is in a manner able to be of service to them. The results in the various institutions bear out the benefit to him in such environment.

The position of the crippled child in the neighborhood school is not always happy. He feels he is pitied and merely suffered; he is not in accord with his surroundings. He is not able to take advantage of the contact with normal children and does not accommodate himself to it. Special schools are a desideratum. The mode of conveyance is a problem for consideration, but this needs but slight improvement as it has been worked out in Boston, New York, and Chicago.

For the child who cannot be transported to and from school and who is no longer a hospital patient, the school board should provide private instruction. These children are better grouped in hospital schools and taught systematically.

My plea therefore is this: (1) Establish hospital schools for all crippled

Underwood & Underwood.

Frequently these little patients are kept for years, but they are taught as well as cured in the hospital.

Underwood & Underwood.

The bed is the workshop, but these little artisans feel the joy of creative work.

pled children needing physical care. (2) Establish special schools for all convalescent and ambulatory patients. (3) Establish work shops for those able to take advantage of them. (4) All these to be established under public supervision.

Their value has been demonstrated. They should be put to universal practice. Following are lists of the state institutions, homes, hospitals, and miscellaneous institutions, and the number of beds in each of institutions that provide a plan for the care of the crippled child:

State Institutions

New York—West Haverstraw, New York State Hospital for Crippled, 125 beds.

Massachusetts—Canton, Massachusetts Hospital School, 300 beds. (educational).

Minnesota—St. Paul, State Sanitarium, 160 beds.

Underwood & Underwood.

The daily exercise of these crippled children are properly adapted to be corrective. Schooling must be provided during treatment if they are not to be doubly handicapped.

Nebraska—Lincoln, Nebraska Orthopedic Hospital, 100 beds.

Homes for Cripples

Connecticut—Newington, Virginia T. Smith Home, 110 beds; Wilton, St. Elizabeth's House, 30 beds.

Illinois—West Chicago, County Home for Convalescent Children, 70 beds; Chicago, Home for Destitute Crippled Children, 118 beds.

Maryland—Orange Grove, St. Gabriel's Home, 50 beds.

Massachusetts—Hyde Park, New England Peabody Home, 40 beds (educational).

Missouri—St. Louis, Summer Home for Crippled Children, 20 beds.

New Jersey—Englewood, Daisy Field's Home and Hospital, 20 beds.

New York—Garden City, House of St. Giles the Crippled, 64 beds; New York, Darach Home for Crippled Children, 18 beds; Southampton, Home for Crippled Children, 30 beds.

Ohio—Cleveland, Holy Cross House, 20 beds.

Pennsylvania—Allentown, Good Shepherd's Home, 56 beds; Philadelphia, House of St. Michael (colored cripples), 37 beds; Pittsburgh, Industrial Home for Crippled Children, 50 beds.

Orthopedic Hospitals

Georgia—Atlanta, National Surgical Institute, 22 beds; Scottish Rite Hospital for Crippled Children.

Maine—Portland, Children's Hospital, 52 beds.

Michigan—Detroit, Michigan Hospital School (educational).

New Jersey—Orange, New Jersey Orthopedic Hospital and Dispensary, 16 beds.

New York—New York, New York Orthopedic Hospital and Dispensary, 242 beds; New York Hospital for Deformities and Joint Diseases, 72 beds; Port Jefferson, St. Charles Hospital for Crippled Children, 300 beds;

Rockaway Beach, Neponsit Beach Hospital for Children, 120 beds.

Massachusetts—Boston, Boston Children's Hospital.

Missouri—St. Louis, St. Louis Children's Hospital.

Ohio—Elyria, Elyria Memorial Hospital; South Euclid, Rainbow Hospital for Crippled Children, 86 beds.

Pennsylvania—Philadelphia, Pennsylvania Orthopedic Hospital and School of Mechano-Therapy; Philadelphia Orthopedic Hospital, 136 beds.

Washington—Seattle, Children's Orthopedic Hospital, 60 beds.

Educational Institutions

Massachusetts—Canton (state), Massachusetts Hospital School, 300 beds; Hyde Park, New England Home for Crippled Children, 40 beds; Boston, Industrial School.

Michigan—Detroit, Michigan Hospital School.

New York—New York, Crippled Children's East Side Free School, 120 beds.

Pennsylvania—Philadelphia, Widener Memorial Industrial Training School for Crippled Children, 112 beds.

Illinois—Chicago, Spaulding School for Crippled Children, 300.

Miscellaneous Institutions

New York—Tarrytown, "Robin's Nest," crippled children, 22 beds.

New York—Society for the Relief of the Ruptured and Crippled, 200 beds.

Study Immigrant Children

The medical inspectors and nurses of the Bureau of Child Hygiene have been directed to trace and follow up immigrant children who have recently been enrolled in public schools. The Bureau will investigate home conditions and connect the family with Baby Health Stations.

Heating and Ventilating of Institutional Homes

Especial Application is Made to Homes for Convalescents, the Aged, and for Children

By JOHN R. ALLEN, DEAN, COLLEGE OF ENGINEERING, UNIVERSITY OF MINNESOTA, MINNEAPOLIS, MINN.*

THE ventilating and heating of buildings for convalescents, the aged, and for children are most important considerations in connection with the health and comfort of the occupants. Not only should a great deal of care be given to the design of the system, whether natural or mechanical ventilation is resorted to, but equal care should be given to the operation and maintenance of the system. Many of the popular ideas in regard to ventilation are found to be incorrect in the light of recent investigations. In general, we are little concerned with the chemical composition of the air. Its physical properties are of far greater value.

does not constitute ventilation in the modern sense.

Body Temperature

In considering the effect of ventilation upon the human system, the lungs may be considered as part of the skin, and as far as ventilation is concerned, perform the same function—that is, the control of body temperature. One of the most sensitive functions of the human body is the control of temperature. A change of a few degrees above or below normal in the human body produces serious physiological conditions. The temperature of the body is controlled by the action of the skin and lungs.

grometer or a psychrometer. This instrument consists of two thermometers of equal reading placed side by side. One thermometer is left in its normal condition and the bulb of the other thermometer is kept wet by means of a muslin cloth dipped in water. The air motion is usually measured by some visible gas or light toy balloons in the room. If the air motion is zero, the determining factor is the wet bulb temperature. As the air motion increases we must increase the wet bulb temperature to maintain comfort. In determining the proper wet bulb temperature for comfort, another factor must be taken into consideration. This is the physical

Chart prepared by Dr. E. Vernon Hill of the Chicago Department of Health for the proper correlation between temperature, humidity, and air movement in the heating and ventilating of buildings.

Chemically, there is practically no such thing as fresh air. All air is substantially of the same chemical composition, and as far as the chemical composition of the air is concerned there is no difference in the effect upon the lungs of the air inside the building as compared with the air outside the building. There is a prevailing idea that ventilation consists of introducing a certain amount of air into a building, but this

This cooling action is controlled by the air passing over the skin and carrying away heat both by contact and by evaporation. The effectiveness of the air in controlling the temperature regulation of the body depends upon the temperature, humidity, and air movement. The chart below, prepared by Dr. E. Vernon Hill of the Chicago Health Department, shows the relation between these three factors in securing the greatest bodily comfort.

The humidity in a room is measured by means of a wet and dry bulb thermometer, sometimes called a hy-

state of the people in the room. The four curves in the chart marked "At rest," "Light work," etc., show how the wet bulb temperature must be varied depending on the physical state of the occupants. In using the chart it is necessary first to determine the air motion which prevails in the room. Let us suppose the air motion is thirty. Find the intersection of the air motion and the line representing the physical state, which in a health institution would usually be "At rest," and suppose intersection of the line of thirty feet air motion with the line "At rest" is fifty-seven.

*Dean Allen died October 26, 1920. This contribution by Dean Allen has been edited by Mr. S. A. Scipio, acting director, American Society for Ventilating Engineers, United States Bureau of Mines, Pittsburgh, Pa.

The humidity readings as taken by a psychrometer are now plotted, using the scale at the top of the chart marked "Dry bulb." The dry bulb is assumed to be seventy. Also assume that the wet bulb reads 61 degrees. By following the line down from 70 degrees in the dry bulb and following across until this is intersected by the line of 61 degrees for wet bulb, we read that the corresponding humidity is 6 per cent. From our previous condition of air motion and physical state we required a wet bulb of only fifty-seven. It is evident that the actual wet bulb is now four degrees too high. This can be remedied in two ways; either by increasing the air motion in the room, or by reducing the humidity. From the study of this chart it may be seen that bodily comfort very largely depends upon the wet bulb temperature and this can be used as a measure of the comfort of a room.

Dust More than a Nuisance

In addition to the factors given above there are three others to be considered—namely, dust, bacteria, and odors. Dust in homes for the aged, convalescent homes, and other similar institutions must be considered more than a mere nuisance. From the standpoint of health this factor is always important and in certain localities it might be a serious consideration. It is in this connection that the problem of proper humidity is of so much importance, especially in certain health institutions where there is no artificial means for humidifying the air. In such buildings, during the winter season, the relative humidity of the air is extremely low, and the result is that moisture is drawn from woodwork, clothing, rugs, and draperies, etc., causing heavy clouds of dust to be carried about the room upon the least agitation. The dust, when breathed, irritates the mucous membrane and its effect upon the nervous system seriously interferes with the convalescence of the patients in these homes. The dust content of the air should be reduced to a minimum by special attention to its accumulation in the room, and if possible, by means of artificial humidification.

Dust must also be considered in connection with bacteria, as much of the bacteria in the air is carried by the dust and not by the air itself. Just what effect the bacteria of the air has upon the health is still unsettled, but of course an excess of pathogenic bacteria must be undesirable.

The last consideration is that of

odors. Odors in themselves are not in general injurious, but their effect is largely psychological, and for that reason they cannot be neglected. Most people judge the condition of ventilation in a building by the odor. It is not an infallible test but you cannot convince a man against the evidence of his own senses. Therefore, it is always an important consideration.

Value of Circulation

As far as temperature, humidity, and air circulation are concerned, there is absolutely no necessity of introducing outside air. These could all be controlled by re-circulating the same air. Most people do not understand the essential reason for opening the windows, particularly in the summertime. It is not to introduce so-called pure air, because in most cases the air in the room is chemically the same as the air outside; but to reduce the temperature and get air circulation, principally the latter. In many cases, where the complaint is made that the air in the room is bad, all that is necessary to improve the conditions is to put in some means of circulation. Circulation is one of the important considerations in ventilation; and it is often lost sight of. If temperature, humidity, and circulation were the only considerations in ventilation, then very little outside air would be introduced for ventilating purposes; but we have the other factors in the problem, such as dust, bacteria, and odors.

The only method in general use to reduce odors is by means of dilution, which necessitates the introduction of large quantities of air free from odor. The disagreeable odors can only be reduced by the introduction of large quantities of air from the outside. This outside air, however, if directly introduced into the room, may produce conditions of temperature and humidity which are very undesirable. It may also introduce dust. It is therefore necessary in any well ventilated building to have the condition of the air under control at all times. This means a properly installed ventilating system must control temperature, humidity, circulation; and in addition reduce the dust, bacteria, and odors to a minimum.

Operating of Ventilating Plant

In many buildings very complete ventilation plants have been installed but have never been satisfactory, largely due to the fact that they have not been satisfactorily operated. The operation of the plant is just as important as its original installation.

Every executive should know or should find out how much his engineer knows about air conditioning and give him the proper apparatus so that he can determine the condition of the air in the various portions of the institution. He should also know that his engineer understands his plant thoroughly, and that he knows how to control the air in the building in order to obtain the desired conditions. In many institutions, the engineer that burns the least coal is the best engineer. This is the same as saying that the surgeon that uses the smallest amount of surgical dressings and antiseptic solutions is the best surgeon. You cannot have something for nothing, and if you desire properly to ventilate a building, you must be willing to pay for it. Do not judge the operating engineer by the coal pile, but judge him by the air conditions in the building. It is not fair to expect a poorly equipped engineer at a small salary to be competent and to understand the operation of a complicated heating and ventilating system which may cost one hundred thousand dollars or more. In large institutions it is important that you have a competent engineer, that he is paid good wages, and then you can demand satisfactory results.

In the state of Minnesota, for instance, the law provides that all school buildings shall have a properly installed ventilating system, but the law does not require that the ventilating plant be operated. The same is true in all buildings where the heating and ventilating system has been well installed and is complete in every detail, but where in many cases the ventilation is turned off either wholly or partly most of the time, and is never properly operated. The furnishing of properly conditioned air to all health institutions is just as important as the water and milk supply, and should be looked after with equal care. The neglect of this phase of operation may be just as detrimental to the patients as neglect of any other factor in the management of a health institution. Much more is involved than merely preserving a given balance in the given chemical constituents of the air. Refinements of observation methods are called for, properly checked by the sensation and well being of the occupants of enclosed places. Many recent contributions have been made to this subject, notably the reports of the observations and improved instrumentation by Leonard Hill, all tending toward a nicer sense of the mechanical and physiological factors.

Minimum Health Standards in Schools*

Scientific Methods of Health Bookkeeping Serve to Disclose Health Hazards

BY LOUIS I. HARRIS, M.D., D.P.H., DIRECTOR, BUREAU OF PREVENTABLE DISEASES, DEPARTMENT OF HEALTH,
NEW YORK CITY

IN THIS article it is aimed to present an outline of minimum sanitary standards for the protection of school children and teachers. The contributions made by various observers to our knowledge of the sanitary and working conditions in schools and their effects upon the health of both the pupils and teachers are very meager. Much valuable information is available with reference to the health of school children as a result of school medical examinations and special studies, but aside from Terman's "The Teacher's Health," there have been no very substantial, scientific or comprehensive contributions on this subject. The health of the teacher determines not only the quality of his services to the individual and to the community as a whole, but is of grave concern to every parent as an index of sanitary conditions in the school environment and because of the intimate contact which necessarily exists between teachers and pupils.

Statistics Misleading

A note of caution should be sounded with respect to certain fallacies that underlie the statistical studies which have been made of the health of school teachers, particularly those dealing with the mortality rate from various diseases among those so employed, as contrasted with other occupational groups. The reports of the Schlockov Committee and of Dr. L. I. Dublin on this subject do not present typical cross-sections which give a fair basis for judgment as to the degree to which the teaching profession is a hazardous one. These studies present but a fragmentary picture covering a limited period of time and, in the main, a record of those illnesses and diseases exclusively, for which the regulations provide compensation or which for other special reasons come under official notice.

Those who venture to offer definite conclusions with reference to the presence or absence of hazards in the school environment and in the teaching profession, on the basis of the

Specific public health problems are bound up with school hygiene because of the large proportion of the ill health of the community which is found among children of school age.

This subject has been covered from the viewpoint of physical equipment and certain fundamental principles of sanitation have been definitely worked out.

Medical inspection of school children has not, however, meant health supervision for teachers and little is definitely known regarding the occupational hazards of teaching either to guide future studies or to serve as a prophylaxis against their menace to health.

available records of the number and causes of illness and deaths, are prone to make the same serious error that frequently is noted with respect to military statistics. The cases of illness and of disease which are published in military statistics are, by and large, those which cause a relatively marked disability. At the close of the recent war, morbidity and mortality statistics were published showing the incidence of disease and of deaths, and their causes, in the army. Since then, however, through various sources—official and unofficial—much additional information has come to light about the many cases of so-called "irritable heart," of mental disease, as well as of thousands who since the close of the war have come to official notice as the subjects of tuberculosis, mental disease, or as suffering from the sequelae of poison gases, of under-nutrition, of severe physical labor and exposure. These as well as other conditions have been responsible for much illness or disability which did not appear in official records. Those who continued in the trenches despite certain more or less significant illnesses were also never reported. Likewise, with respect to statistical studies of teachers.

What is now required is a study

that will reveal not only the cases of illness in teachers which come to official notice, but also those others which have a serious effect upon the physical and mental well being of teachers and which may affect their capacity to teach and the quality of their work. We should know how many of these teachers persist in remaining on active duty in the trenches, so to speak, despite ailments and illnesses which affect them, and who thus really "malingering" or pretend to the possession of health which they have not. Such studies should cover an adequate span of years and should subdivide the teachers who form the subject of such studies, not only according to sex, but into the various age groups, so that we may record whether they are subject to a variety of diseases which are directly or indirectly caused by their vocation, and particularly whether such diseases appear in a relatively early age group. In other words, whether they suffer prematurely from the effects of fatigue, of any specific diseases, or from the result of exposure to insanitary conditions. The cases of illness should be studied and referred back, if possible, so as to learn whether there is an association between a particular type of illness or disease or cause of death, and the conditions obtaining in respective schools.

Such studies should aim to determine how much of the "labor turnover" or the desertions from the ranks of the profession are due to discomfort or ill health induced by the nature of the work. As the result of their experience, industrial hygienists invariably ascribe a certain amount of labor turnover to conditions in industry which have a relation to health and comfort. In such studies, emphasis should not be laid merely upon the number of deaths or even upon the number of cases of illness from various causes, but special consideration should be given to the question whether the work in a given group or type of teachers is compatible with "keeping fit" so as to enable the teachers to enjoy normal and healthful life. Further, such studies should not be rated as com-

*An address delivered before the Teachers' Union, New York City, March 17, 1921.

plete unless they are based on the most careful clinical observation of a large number of teachers over a considerable period of time, so as to measure more accurately the effect upon the general powers of resistance and general well being, as well as upon the nervous system, the heart, the digestive system, the lungs, and the other parts of the body, of the work that they are doing. Due consideration should of course be given to any personal habits, unusual home conditions, or to a physical condition antecedent to entering the profession, which may have exerted an influence in causing certain clinical conditions which may be observed in the course of such studies.

In the slow evolution of things, the necessity for the medical examination and supervision of school children has become recognized by civilized nations and by the more progressive communities. We must be sure that school children who are being medically examined for the discovery and correction of physical defects are not in the meanwhile subject to environmental conditions within the school which may in greater or less measure be responsible for the development of such or of subsequent physical defects and disease. Therefore, the sanitary conditions of the school environment and the health of the school teacher who comes into such immediate contact with school children, are interlocked, and must be most carefully considered together.

The school teacher who suffers from a communicable disease, such as pulmonary tuberculosis, is a most grave menace because of the intimate contact with relatively large numbers of children, who, as medical men well know, are most subject to tuberculous infection. Therefore, the sanitary conditions prevailing in schools which may favor the development of tuberculosis or other communicable diseases may be of very great significance from the standpoint of their influence upon pupil and teacher. Moreover, ill health may have a very serious effect upon the disposition and temperament of school teachers and may seriously influence their work in molding the character of the pupils under their care.

With our gradual advance in medical knowledge has come a better understanding of the particular significance of fatigue, not only as the cause of mental strain, of so-called "neurasthenia," but as the cause of a direct or indirect reaction through nervous channels upon various organs and glands in the body, whose com-

plex actions are delicately balanced and correlated so that a disturbance of one such organ or gland may radiate to many, and cause perversions of circulation, and of many of the vital processes of life. We have also come to appreciate that the powers of resistance of the body which determine how susceptible an individual may be to any one of the communicable diseases, are very seriously affected and undermined by fatigue. Fatigue, therefore, aside from causing certain nervous or mental disorders may play a serious role in influencing the development of a variety of organic diseases, or in predisposing individuals to communicable diseases.

Fatigue is not only determined by the number of hours of work, or by the number of days of work each week, but depends to a great degree upon the character of such work. It is especially induced by the necessity of concentrating, and taxing the powers of attention, memory, and alertness. For example, everyone who has had experience in studying fatigue in industry has given attention to the strain upon the girls engaged in the process of weaving who may have to take care of twelve or even more looms at a time, or upon girls doing similar types of work which require them to tend to from twelve to thirty or forty units of machinery at one time. In like fashion each pupil may justly be regarded as comparable to a unit of machinery insofar as it taxes and strains the mental and visual faculties and causes a physical effort connected with speaking to a large group. No one, except those who have done public speaking or teaching continuously for prolonged periods can appreciate the physical as well as the mental strain which constant loud speaking may cause. Fatigue is greatly aggravated by any insanitary condition which may obtain in the school or classroom. Excessive heat, poor ventilation, inadequate lighting, dust in the air,—all of these, and many other environmental factors tend to aggravate as well as to induce fatigue.

In industry, it has frequently been possible for experts who study fatigue, to recognize its presence and to estimate its degree, by the amount of spoiled work which is produced by those who are suffering from this condition. Unfortunately, this test cannot be applied in dealing with that intangible product of the teachers' labors,—namely, knowledge and character development. It would be of inestimable value if "spoiled work" of teachers, as the result of the fatigue from which they may be

suffering could be even approximately estimated. Because of its tremendous significance and value to the life of the community and of the individual. It would be most valuable to know how many children were unfavorably influenced with respect to the acquirements of character and knowledge or were "spoiled" or marred in the process of their making as the result of fatigue in the teacher. Unfortunately, it has been found that workers themselves are not always conscious of fatigue, nor are their sensations a reliable guide as to its presence. For these reasons too much stress cannot be laid upon the importance of having proper and sanitary environment, so that children who spend a considerable part of their growing years in the school environment shall not be unfavorably affected by insanitary conditions,—and teachers likewise,—and so that such conditions of work shall not be productive of fatigue which may cause a marked susceptibility to disease in both pupil and teacher or be reflected ultimately in the character of the children who came out of our schools.

While tuberculosis is not a conspicuous hazard in the teaching profession, it must nevertheless be reckoned with as a most important disease to which teachers are in a fair measure exposed and subject. No adequate scientific work has yet been done under proper medical direction to ascertain to what extent the physical condition of teachers before they enter upon their profession, or the home conditions, the school environment, or the exposure to conditions which may favor the development of bronchitis or respiratory infections, as well as personal habits, may each contribute to call into activity a latent tuberculous infection which most adults harbor, and cause an active process to be lighted up. In the study made by Dublin of morbidity and mortality statistics which were available through official sources, he pointed out that only thirty-eight teachers in New York City had pulmonary tuberculosis during 1915. It is reasonable to suppose that the thorough and systematic physical examination of our school teachers would have revealed a very considerable amount of tuberculosis that had not previously been recognized or disclosed. Pulmonary tuberculosis, even if there be but thirty-eight cases of it among school teachers, is a much more grave condition in members of this profession, who come in such direct and intimate contact with great masses of children, than is indicated

by its numerical prevalence. The tuberculous teacher is potentially a distributor of such infection to all of his or her pupils because, as already mentioned, childhood is the age of greatest susceptibility to tuberculosis.

While there is much that is indefinite with reference to the prevalence of specific occupational hazards or diseases among teachers, because of the fallacious methods of inquiry upon which we have heretofore had to depend for our statistical knowledge, one may, however, state quite definitely on the basis of statistical evidence that tuberculosis, chronic laryngitis, or "speaker's voice," nervous disorders which assume a variety of forms, especially so-called "neurasthenia," digestive disorders, respiratory infections—notably acute bronchitis, influenza, pneumonia and follicular tonsillitis—as well as defective eyesight, and in some, female menstrual disorders, may be properly regarded as occupational diseases incident to teaching.

Neurasthenia and other nervous disorders have already been referred to as being very frequent among school teachers; it is fair to assume this prevalence, not only on a statistical basis but also because they have been found to be most markedly prevalent among skilled workers in various other professions and trades. As already briefly indicated, the nervous manifestations may cause reflex disturbances, as of the digestive organs, or, generative organs (in females). Such nervous disorders may be temporary in character, or they may become firmly and permanently established. Acute infectious diseases would no doubt be found to be relatively frequent, if the health of teachers was studied, not merely by means of the compilation of inadequate statistics, but by continuous medical supervision, and by follow-up to as-

certain the cause of absences. The intimate contact of teachers with children, who, as it is well known, are especially susceptible to a variety of acute infectious diseases, make them likely to contract such diseases.

Chronic laryngitis has been very frequently found among teachers, as indeed among others who are compelled to use the voice a good deal. This results in hoarseness and very considerable discomfort, and may be followed by a secondary bronchitis, resulting from extension of inflammatory conditions affecting the larynx and the pharynx. Laryngitis, and acute or chronic bronchitis, are in a measure capable of being caused as the result of exposure to chalk dust. Dr. George M. Kober in his latest work—Occupational Diseases, by Kober and Hanson—has particularly emphasized the hazard from chalk dust not only with relation to bronchitis, but with reference to the development of pulmonary tuberculosis. In reviewing the prevalence of tuberculosis in teachers which some writers have reported as being comparatively low, he says:

Higher rates for tuberculosis have been reported by Schmidt of Dusseldorf (than death rate of 1.3 males and 1.55 per 1000 females in Bavaria) and our American statistics also indicate that school teachers are slightly more liable to tuberculosis than members of the other learned professions.

This is doubtless due to indoor life, confinement in badly ventilated school rooms, and the presence of dust. Diseases of the nervous system and uterine organs are also quite common, and teachers will do well to insist upon proper seats, absolute cleanliness of the school room, fresh air schools, or at least copious ventilation, and substitution of wet for dry methods of removing chalk markings.

Defective eyesight is very commonly found among school teachers and, while no doubt it is in a measure due to the strain upon the eyes in the

course of preparation for their profession, it may also, however, be produced in a very considerable number of cases by the strain to which sight is subjected in the course of routine work and particularly by defects of lighting. While there is insufficient evidence to warrant many of the statements which have been made with reference to the prevalence of certain diseases among teachers, one may nevertheless venture to assert that thorough and frequent medical examination of many teachers over an extended period of time, with a scientific method of health bookkeeping, would show the existence of numbers of organic defects which have not thus far been recognized or justly appraised. Surely, the glib dismissal of diseases said to be associated with teaching which has sometimes marked the reports of certain studies based on manifestly inadequate statistical evidence, is not scientific and has tended, unintentionally no doubt, to treat these moot points as if they had been settled conclusively and for all times.

In marshalling statistics one must be cautious in their use and in their selection that they may not consciously or otherwise be pressed into service to bolster up fixed preconceptions. As illustration one might balance against some statistics which have been published to discount the existence of occupational hazards in the teaching profession, the report contained in Bulletin No. 106 of the United States Bureau of Census for 1909 in which it is shown that in certain age periods, the mortality of teachers from certain infectious diseases and from organic heart and kidney disease is higher than for the general mass of females in industry. The point to be emphasized is that available data can be of service as a useful guide in planning scientific and thorough studies in the future.

The Association Cafeteria*

THE Y. W. C. A. cafeteria is a many sided institution. Conceived originally as a necessary service to business girls of limited time whose means would not permit them to secure dainty and wholesome food at sumptuous refectories, its aim was to provide the best foods on the market at the cheapest price it could be had.

It has long been recognized that the quality of the day's work is largely influenced by the kind and quality of food eaten day by day, purely for the sake of efficiency and as a commercial tool, many industries have supplemented the workmen's lunch box by the provision of warm and substantial midday meal. The Y. W. C. A. has done more than this. By establishing Association cafeterias at convenient points they have made sure that the meals of the working girl may be eaten in a pleasant place. No longer need her food be eaten behind the counter, in the dressing or toilet room, the work bench, or in the workshop atmosphere. The half hour spent at lunch in an Association cafeteria is a half hour of rest and recreation and, aside from the pecuniary success that has attended the enterprise, the cafeteria has been a boon to thousands and a real philanthropy in extending the spirit and hospitality of the Association.

A Practical Manual

The "Handbook of the Association Cafeteria" is a valuable manual, compiled by Blanche Geary, which sets forth clearly under appropriate sections the standards arrived at in the organization, details of arrangement, and the administration of the Association cafeterias. The compilation is calculated to serve anyone in launching such an enterprise. The principles it has evolved are fundamentally sound, for, while these well known eating places have been a highly effectual channel for extending the welfare activities of the Association, the department has been a money making venture. Its success has been achieved in a difficult field and is contingent upon pleasing the quizzical public on a competitive basis with purely commercial enterprises.

The first essential in the location of a cafeteria is that it be central. This is necessary in order to reach quickly and economically those whom it is in-

tended to serve. Another important consideration is that the location, to be right, must be self-advertising. On location, perhaps as much as on good cooking, says Miss Geary, depends the size of the daily attendance. The two together spell profit.

Opinions differ in regard to the spaces required for the service and preparation of food. Some allow a space of eight square feet per person, while others claim that ten, twelve, or even fourteen square feet per person. The ceiling should be not less than fourteen feet high, and more if possible. The cafeteria counter needs to be placed in right relation to the kitchen, and must allow at least eighteen inches for each person standing in line at the service counter.

Details of Equipment

Tables with pedestal in the center are desirable, as the chairs will not then be marred as they are when bumped against table legs. The usual size of the table top is two by 2½ feet for two persons and 2 feet 6 inches by 3 feet 2 inches for four, with a four foot space between tables for seating and three to three and one-half feet for gangways. The table top will be of wood, waxed, if inexpensive equipment is necessary; or of marble, white or black carrara glass if the best looking top may be had. Chairs must be strong, of light weight, without arms, and with a foot rail. Bentwood chairs are light and durable.

The checker's table and chair, the cashier's table and counter, and all arrangements for employees, whether high in price or inexpensive, are chosen with due regard to removing all undue strain. The water supply should be easily accessible from all parts of the room, and should be so arranged as to be clean and attractive at all times. The booklet sketches ideal layouts for both one and two way service, with definite specifications for steam stable, dispensers of various kinds, dish carriers, etc.

Precautions are always to be made in regard to plumbing. All pipe trenches should be boxed and provided with movable covers so as to be easily reached in case of trouble. Great point is given to the instruction of architects in regard to waterproofing the floors below the dishwashing space. The keenest judgment needs to be exercised in the placing of equipment. It is to be remembered that cooks radiate heat as easily on the cook's back as on

the salad table and that the size of the ice bill is closely related to the range in many kitchens, and that for want of planning, the garbage man and the scrubbing woman are often not on speaking terms.

Especial warning is issued not to over-equip. The cost of cleaning and repair is to be considered in securing and placing equipment, and every inch of space counts. Minute specifications are necessary in regard to the major considerations of refrigeration, ranges, working paraphernalia, and storage, but it is not to be overlooked that efficiency hinges also upon the provision and proper equipment of the cook's and scrubwoman's closet, and of the janitor's workroom.

Quantities of Equipment

Equipment is required for one-third of the total service; twice as many teaspoons as forks will be needed, the silverware to be of the best triple plate of a simple design. Linen napkins are appreciated by the public and should be provided; the china should be harmonious, while some experts prefer a smaller size in each case, the Y. W. C. A. standards call for the following sizes: Dinner plates, 9 inches; breakfast plates, 7 inches; soup bowls, 6 inches; cups of teacup size; cream pitchers, 1½ ounce size; fruit saucers, 5 inches; butter pats, 3 inches.

The efficiency of the plant ultimately depends upon the cafeteria director. Her office should be within easy reach of the kitchen and dining rooms, and she should be in touch with every detail having to do with help, distribution of duties, purchasing of supplies, state of the accounts, the preparation of menus, and general administration. She needs to have personality plus technical training, and the knowledge that is gained only by close contact with the plant.

Health Supervision at Algonquin

To safeguard the health of the people at Camp Algonquin whose expenses are paid by the Chicago Tribune Club, a medical staff of twelve of the leading physicians of Chicago, Oak Park, Elgin, and Cary, Ill., has been provided in connection with the *Tribune* Summer Hospital for Convalescents. Representatives of the Chicago Dental Society met with the staff to develop plans for the care of the teeth of the campers. Two dentists will correct whatever faults they may find, make recommendations for their care, and give lectures on dental hygiene.

*The materials of this comment are drawn from the "Handbook of the Association Cafeteria," by Blanche Geary, published by the National Board of the Young Womens Christian Association.

Standards of California Children's Institutions

THE whole field of child care in the institutions of California has been covered in a recent study out of which have evolved definitions and standards of practice. Herewith are presented the standards as adopted in April, 1921, by the State Board of Charities and Corrections of California:

(1) *Definition*.—A children's institution shall be defined as a place for the reception and full time care of (fifteen or more) children, the support of which is derived in whole or in part from public or private benevolence.

(2) *Governing Board*.—Where there are over fifteen children, the place shall be incorporated with a board of directors of at least seven members, at least four of whom shall be residents of the city or town in which the home is situated. The governing board must be responsible persons who feel a definite interest in the work and give personal attention to it. Board members failing to attend three successive meetings without good excuse should be dropped and replaced by persons who are able to give more time to the problems of the institution.

The meetings of the board of directors shall be held at the institution. The work of the board should be done, on the whole, through committees. These should be working committees, not merely nominal groups, and should include committees on admission, dismissals, finances, house, recreation, etc.

(3) *Buildings*.—The building shall meet the legal requirements of the county in which the institution is located, as to construction, material, safety, lighting, ventilation, sanitation, and fire protection. The upkeep, and particularly the housekeeping, shall conform to the average of the institutions of like character of this state.

Dormitories shall provide a minimum floor space of thirty square feet per child. Furthermore, there shall be a space of at least three feet between the sides and two feet between the ends of beds. The height of the ceiling shall be at least nine feet. The window space shall measure at least one-eighth of the floor space.

Plans for new buildings or parts of buildings must be submitted to the State Board of Charities and Corrections for approval before any contracts are let or work begun.

(4) *Physical Care of Children*.

(a) A nourishing and properly balanced dietary shall be provided, a minimum of one pint of milk daily to be allowed each child.

(b) Formulas for feeding infants should be prescribed by a registered physician.

(c) There shall be frequent and systematic bathing of the children.

(d) A separate bed shall be provided for each child. Each bed shall have a good spring, clean comfortable mattress or its equivalent, and adequate bedding. Rubber sheeting when necessary.

(e) Individual toilet articles shall be supplied each child.

(f) The clothing of the children shall be clean, neat, and seasonable, and of a design, quantity, and quality to develop the self-respect of the child. Clothing should not be used in common. Each child should have his own supply.

(5) *Medical Care*.

(a) A properly equipped infirmary, as well as isolation facilities, shall be provided.

(b) All entrants shall be segregated for a period of fourteen days following admission.

(c) A thorough physical examination, including nose and throat cultures, shall be made of each child by a competent physician prior to its admission to the institution, or during its detention in isolation quarters. This should be followed by remedial treatment when necessary.

(d) Vaccination of all children shall be enforced.

(e) Mental tests shall be made in all doubtful cases.

(f) Frequent and regular examinations of all children shall be made by a physician or licensed nurse.

(g) Institutions with a population of more than 100 children should have a trained nurse in residence.

(h) Dental examinations shall be made at regular intervals and corrective work done promptly. Tooth brushes shall be provided and their use enforced.

(6) *Education and Recreation*.

(a) The education should conform with the requirements of the state and all teachers of the regular curriculum shall be duly licensed.

(b) Children shall receive moral and religious instruction, provided that no child shall be required to attend religious services or to receive religious instruction in a faith differ-

ent from that of its parents or guardian.

(c) A library of books suitable for the use of the children shall be provided and shall be regularly accessible to them.

(d) Playgrounds and playrooms, properly equipped with apparatus, games, and toys shall be provided.

(e) It should be the duty of some one officer of the institution to supervise and encourage play activities.

(7) *Discipline*.—There shall be no corporal punishment.

(8) *Classification of Children*.—Definitely wayward or feeble-minded children shall not be admitted to an institution primarily for the care of needy normal children.

(9) *Supervision*.—The superintendent shall be a person of such character and capacity as shall guarantee to the children control and companionship, and to the board and the state the responsible management of the institution and its inmates. He must not be required to collect funds, but should devote his time to the organization and conduct of the work of caring for the children.

(10) *Admission and Discharge*.—A careful investigation of each application for admission shall be made, to determine whether the best interests of the child will be served by admitting him.

A definite plan for follow-up of children discharged from the institution should be instituted.

(11) *Accounting*.—All accounts shall be kept in conformity with the methods prescribed by the State Board of Charities and Corrections.

(12) *Records and Reports*.—Each institution shall keep individual social and medical histories of each child on the blanks prescribed by the State Board of Charities and Corrections, and shall render annual financial and population reports on the blanks prescribed and furnished by the State Board of Charities and Corrections.

Mississippi Valley Conference On Tuberculosis

The ninth annual session of the Mississippi Valley Conference on Tuberculosis is called for September 12, 13, and 14, 1921, at Columbus, O., with headquarters at the Hotel Deshler. Programs of this kind become more and more vehicles of popular instruction in matters pertaining to public health.

Open Air School on Hotel Roof

Underwood & Underwood.

An exclusive hotel in San Francisco has established an open air school on the roof. This makes it unnecessary for the children to leave the hotel at any time, and avoids the risks incident to passing the traffic on the crowded streets. Kindergarten and primary classes are conducted, and dancing is taught. This scene is in the classroom during play hour.

Mental Measurements in Health Program

Significant deductions are made by E. J. Pratt in the April issue of *The Public Health Journal* on "Mental Measurements as Applied to a Toronto School." The object of the survey was (1) to estimate the mentality of the school as expressed by the Intelligence-Quotient of the individual children, (2) to discover by systematic groupings of the quotients, any correlations between mentality and social status, sex, nutrition and other factors supposedly related. The final aim of the survey was to correlate intelligence data of the children with their efficiency when later they enter industrial life.

Out of approximately 60,000 children investigated, over 1,000 children, something under 2 per cent of the total enrollment, presented problems of mental defect. The intelligence tests were supplemented by observations as to emotional peculiarities and the conclusions were drawn from 502 children examined, in whom supplementary information was procurable.

The results show conclusively the effect of social status upon intelligence. The professional class, for instance, furnish no mental defectives at all, and no mental retardation below 80 Intelligence Quotient. The children whose parents were day la-

borers comprise 45 per cent of the total; artisans, employers, etc., made up 52 per cent. Whether this higher Intelligence-Quotient in the better economic classes is due to hereditary or environmental conditions is a problem requiring more data for discussion.

Malnutrition was found in this series to bear a very marked relation to retardation and the statement is made that 40 per cent of the children suffered from malnutrition to such a degree as to cause a loss of nervous energy. In connection with malnutrition, the statement is further adduced that children of superior stock and intelligence seem to withstand the strain of malnutrition successfully. It was upon the lower levels that malnutrition had its greatest effect. Malnutrition as related to feeble-mindedness is a medical and biological problem requiring extensive inquiry.

As standardization in the field of mental tests is a comparatively recent development in psychology, there has not been much opportunity to study side by side, in statistical form, the industrial records of adults with the mental co-efficients of the same persons or children attending the public schools. A comparative inquiry into such results would be a factor not only in increasing the efficiency of school methods, but also in deter-

mining to some extent the selection of trades and professions, and would affect, reciprocally, the tests themselves.

Trade War Masks As Public Health

The principles of conservation are far reaching in their application and include, along with saving in times of plenty against successive periods of dearth, measures to preserve in useful by-products materials which would otherwise be an economic waste. It is particularly along the latter lines that research work on national nutrition is being given such emphasis at the University of Oregon, and that the National Research Council's Committee on Food and Nutrition has recommended in its recent report a program for a national institute of nutrition.

In view of the need to apply scientific management to matters pertaining to the food supply, it is particularly inopportune that ill advised opposition from competing interests should attack, with specious arguments to Congress against pending legislation which opposes the marketing of compounds of skim milk and vegetable oil. So far as we know, these articles are honestly labeled and are advertised for what they are. They are not to replace certified products for infant feeding, but are specifically recommended for cooking and baking; if wholesome, edible, and frankly labeled, they make available an inexpensive food, and every consideration of public health and economics favors such mixtures.

Legislation against such products was attempted in the states of Washington, New York, New Jersey, and Pennsylvania, where the bills failed of enactment, and the present legislation in Congress must be regarded as directed toward the extermination of products of this character without justification from the public health standpoint.

Creation of Milk Laboratory

The Government has created a branch of the council of departmental administration called the laboratory for the inspection and analysis of milk, with the following duties: The analysis of the milk sold to the public; the analysis of substitutes for mothers' milk; the analysis of products obtained by the use of lactobacillus; and the analysis of the milk of wet nurses. The laboratory will establish a standard to be maintained.

Social Work Among the Physically Handicapped

**Solution May Be Expected to Follow
a Definite Estimate of the Problem**

BY WILLIAM T. CROSS, SURVEY OFFICER, STATE DEPARTMENT OF PUBLIC WELFARE, CHICAGO, ILLINOIS

REHABILITATION as a common objective, or measure, of the varied types of community effort for the individual, is just shifting into focus. The passage of the Federal law and of thirty state acts for the rehabilitation of persons "injured in industry or otherwise," makes it desirable to inquire into the nature of the rehabilitation process. The term has been used for several years by those engaged in family social work. It will require reinterpretation, however, if it is to represent the underlying principle of work for physically handicapped persons. For the social worker it may come to signify a program which welfare agencies share with the doctor, the teacher, and the industrial manager; for the latter it may, in time, suggest a relation with the patient, the "trainee," or the employee, in which

Last Thanksgiving the United Charities of Chicago issued a circular containing fourteen pictures of situations calling for charitable assistance. Among these were the five situations illustrated in this article, used through the courtesy of that Organization.

Social case work often discloses an insurmountable handicap at the point of destitution. In the case of military and civil injuries, prevision and rational preventive measures can avoid the social and individual wrong involved in needless dependencies.

setting their handicap, is without question one of the greatest gains in recent years in constructive community policy.

A Natural Sequence

A natural sequel of wartime developments is the prominence of state and national governments in the early stages of the movement for the rehabilitation of the civilian handicapped. Under the plan established in the Fess-Kenyon Act, guidance and partial support is to be expected from the Federal Board for Vocational Education, according to the method of Federal aid to vocational education

end results are kept more constantly in view.

As At First Conceived

The ideas of physical handicap and of rehabilitation first impressed the popular imagination when the country was struck with the pathetic vision of thousands of its young men disabled in the war. These ideas were a constructive substitute for the morbid thought of affliction. Alternatives were pensioning and national waste. Rehabilitation meant the conservation of man power. The definition, as a class, of those whose physical disabilities obstruct their economic and social functioning, and the formulation of a procedure for off-

The laborious efforts of this breadwinner are the sole means of maintenance of her family, including a sick husband.

The undernourished child is a fit subject for social study and remedial activities.

The father of this destitute family is afflicted with heart trouble and unable to work

in the states. Several states have made large appropriations to establish bureaus of rehabilitation. For the future it is important to inquire in what ways governmental methods may need to be adapted in dealing with problems of personal development and at what points they may need to be supplemented by that co-operation of individuals and voluntary agencies which is fundamental to all government undertakings.

Plan Should Suit Purpose

The purpose of the state is, by any means that may succeed with the handicapped person, to raise him permanently out of the class of community liability. The preferences of the individual must be consulted at all times as a matter of expediency. His maximum restoration physically, which is the starting point for plans of education and of employment, can be undertaken directly by the state only in a small proportion of cases. Formal training vocationally is impractical for a large percentage of the civilian handicapped because of their age, their degree of intelligence, their family obligations or other circumstances. The final step in rehabilitation, employment, depends upon the opportunities that may present themselves in a given community. In dealing with the disabled man's desires and with the requirements of private employers, only those plans that are plastic and adaptable are likely to be effective. The limitations of public activity are apparent.

That circumstances seem to require in some cases a plan of expe-

diency and adjustment within a congenial environment is illustrated in the experience of Butler James:

When Butler James sat down at the interviewer's desk, it was not observed for some time that he lacked both hands. He was colored, was twenty-three years old, and was married. His only child had died when a few days old. His wife was traveling with a white family, as a practical nurse. She was loyal to him. James had just been paroled from the state reformatory.

In his boyhood, he had lost his hands at the wrists, as a result of hopping trains. He migrated north to a large city, and fell into the drift of the unskilled, eventually being employed in the stockyards under con-

ditions which brought on rheumatism. His will was weak and his companions were bad. He participated in a robbery and was given the two-year sentence from which he was now returning. In the reformatory he had been given some schooling, but he had not been taught a trade. A psychiatric examination showed him to be eleven years old mentally. However, James had poise and an affable manner which tended to offset any backwardness and his evident laziness. He dressed carefully, in spite of his lack of hands, and said he was dependent on others only for tying his necktie.

A messenger's job was secured through the public employment bureau. At this he gave satisfaction for only a month. He was ambitious to go to Tuskegee Institute; however, the necessity of maintaining his family was recognized, and his lack of education seemed to make it more desirable to try for a business connection at once. He showed good sense about questions of management. He discovered a bowling and billiard establishment in which there was opportunity to set up a shine stand. With financial aid from interested groups, this was done. The head of the establishment took a personal interest and ways were found to make the arrangement pay, capitalizing James' capacity for getting on with patrons and employees, rather than his handicap. The work corresponded with the boy's wishes, and the sporting atmosphere harmonized with his early training and his temperament. In the large establishments were other positions to which the man might advance.

Analysis Called For

Shortly after the war I met an industrial engineer who had carried on an extensive survey preparatory to the employment of wounded soldiers who exhibited a certain type of dis-

Only intelligent social effort can save this family of a tuberculous father from the direst need

ability. By means of time and motion studies, and job analyses of standard industries, he had demonstrated that ample opportunity could be found for employment of men with this disability, according to the various gradations of mental type. But, when the war was ended, there did not appear an appreciable fraction of the number with this type of disability for whom possibilities of employment had been so carefully charted. In those cases that did occur, the men were not inclined especially to take up the pursuits that had been surveyed. The industrial engineer was aware that many hundreds of persons with this type of disability existed in the civilian population, but individually they did not follow any pattern of mental ability, age group, desire for employment, location, and family situation that would make possible a standard procedure of adjustment on the job, and the man was discouraged.

The rehabilitation of physically handicapped persons can be accomplished extensively only with the aid of some procedure which is built upon the differences in human nature and in life situations. It would be accomplished with the least expenditure of money and effort if all cases fell into a small number of classes, and if there were some assurance that the performance of specified medical and educational services would secure the results desired. Among cases of handicap in any community, however, problems of adjustment do not repeat themselves in identical form. Some are aware chiefly of their medical needs, while others are most concerned with getting a job. Handicapped persons frequently are diffident about receiving any constructive assistance because of false conceptions regarding their disabilities. They cannot be imagined as standing in line before a registration desk, ready to undergo any standard process of adjustment. Rehabilitation in each instance means finding the water, leading the horse to it, and perhaps making him drink.

Social Survey Necessary

A procedure of dealing with varieties of human situations has developed in social case work. Where the medical, or vocational, or industrial agency is concerned with individuals, somewhat apart from their environments, the social case worker is accustomed to the treatment of the man in connection with his family and larger groups. The conditions which differentiate one case from another

This man was a hard worker, but an industrial accident made him permanently helpless.

are to him not a source of obstruction or confusion; they are the basis of his plan of treatment. A man's desires and his type of behavior are, by the social worker, continuously and persistently correlated with his economic success. In this way the technique of the social worker is adapted to the prolonged and composite kind of service that is necessary for ultimate rehabilitation.

Public Health Nurses in Brazil

Brazilian journals are commenting very favorably on the introduction by Dr. Chagas of public health nurses. While their number is limited and their introduction comparatively recent, the results already shown from their work have impressed the public very favorably, according to the *Journal of the American Medical Association*, July 9, 1921.

The Welfare of the Foreign Born

International Film Service, Inc.

Prominent club women of Chicago have undertaken to induct foreign-born mothers on the West side into the fine arts of domestic science. Keen to learn, the mothers are guided into new ways that lead to better adaptation of their households to new conditions of living in a foreign land. In this picture the children of these mothers are shown under the care of trained nurses in the station at 1415 Blackhawk Avenue.

Cooperative Health Plan in New York County*

The New York County Chapter of the American Red Cross Has Affiliated All Existing Health Agencies

BY GEORGE R. BEDINGER, DIRECTOR, HEALTH SERVICE, NEW YORK COUNTY CHAPTER, THE AMERICAN RED CROSS, NEW YORK CITY.

TO STRENGTHEN and support existing Public Health Agencies is not only the aim, but also the achievement of the New York County Chapter of the American Red Cross since it entered the field of public health eighteen months ago. The Chapter's new Health Service was organized in January, 1920, as the result of a careful report made to the Executive Committee by a special committee¹ appointed to consider what activities, if any, the Red Cross on Manhattan Island should undertake in the field of health.

This Committee strongly urged the Chapter to make Public Health Work in the aid and coordination of existing Public Health Agencies, the major peace-time activity of the Red Cross. The Committee's report was unanimously approved by the Executive Committee of the Chapter, and this group of health experts has continued as the permanent Health Service Committee of the Chapter. Dr. Livingston Farrand and Dr. Erwin A. Peterson of National Headquarters, American Red Cross, are ex-officio members. The program of the Red Cross Health Service as outlined in detail by this Committee consists mainly of a broad statesmanlike plan of public health education and information, under which the Red Cross is performing certain joint services for the public health agencies of the city, activities which it would be difficult for any one agency to do so well for itself alone.

Among these common services,

offered without charge by the local Red Cross Health Service, are:

(1) A Bureau of Public Health Information through which any interested person can secure up-to-date information in regard to all phases of Public Health activity in New York County. That this Bureau fills a real need is shown by the fact that since its opening on March 31, 1920, the number of questions and specific requests for health literature has reached a total of 8,862. This health information is being constantly kept up-to-date.

(2) Real Red Cross cooperation is also shown by our assistance to agencies in the production of their Health Leaflets.

The Red Cross has already made possible the printing, in answer to direct requests, of more than eight hundred thousand health leaflets. The eight agencies for whom we have been privileged to do this service thus far are: The New York Tuberculosis Association, The Maternity Center Association, The Association for

Relief and Prevention of Heart Disease, The New York Urban League, The American Social Hygiene Association, The Child Health Organization of America, the New York Nutrition Council, and The Federation for Child Study.

(3) Another cooperative enterprise is a Health Speakers Bureau, designed to "act as a clearing house through which all public health agencies can find opportunities for their lecturers to speak, and through which local groups of any kind desiring to arrange public health lectures, can secure qualified lecturers, or a series of lectures, if desired."

This Bureau, organized in the New York County Chapter in May, 1920, and in the Brooklyn Chapter in July, 1920, has arranged 926 health talks to June 1, 1921. One hundred seventy-two speakers from eighty-four agencies have supplied these talks without fee. The estimated attendance at these health talks arranged by this new Bureau is 128,737. Many organizations wished a series

The East Harlem Health Center is a demonstration in cooperative health work, where various agencies exercise complete autonomy in their several fields, but are brought together for administrative purposes. Planned as a national health demonstration, every facility is provided to test the efficacy of the method.

*Read before the Division of Health, National Conference of Social Work, Milwaukee, Wis., June, 1921.

1. This Committee is composed of the following: Dr. James Alexander Miller, chairman, president, New York Tuberculosis Association; Dr. Hermann M. Biggs, New York State Commissioner of Health; Mr. Bailey B. Burritt, general director, Association for Improving the Condition of the Poor, New York City; Dr. Haven Emerson, former Commissioner of Health, New York City; Mr. Homer Folks, secretary, New York State Charities Aid Association and former Executive Officer, New York County Chapter, American Red Cross; Mr. John M. Glenn, director general, Russell Sage Foundation; Dr. L. Emmett Holt, chairman, Child Health Organization of America; Dr. Edward L. Keyes, Jr., president, Medical Board, St. Vincent's Hospital; Dr. Thomas W. Salmon, general director, National Committee on Mental Hygiene; Dr. William F. Snow, general director, American Social Hygiene Association; and Dr. Philip Van Ingen, chairman, American Child Hygiene Association.

of five or more talks arranged for them. I am glad to report to the Conference that the Health Speakers Bureau organized by us in the Brooklyn Chapter has made a larger record than the parent Bureau in New York County. The types of audiences can be imagined when it is known that these talks were distributed as follows: Churches, seventy-four; settlements, twenty-three; "Y's," thirteen; schools, thirty; shops, fifty-six; miscellaneous, thirty-two.

Services Are Various

Let me mention two other Red Cross services designed to assist public health activities.

(4) Up-to-date mailing lists of groups interested in various phases of the Public Health Program, have been compiled and placed at the service of other agencies. The total number of names included in the twenty-two mailing lists which have been carded and stenciled is now 9,712. Included in this list of associations, churches, clubs, schools, health and social agencies, etc., is a very valuable consolidated list of directors and executives of eighty public health agencies numbering 1,206 names and a list of employers having a health service numbering 780 names. These lists have been used 272 times by fifty-one different organizations.

(5) A personnel center for volunteer workers in various health connections, such as clinical secretaries, assistants in nutrition classes, maternity centers, etc., is in full swing. It was begun by the Health Service and is now under the Department of Volunteer Service. During the last twelve months 342 volunteers have been assigned for health work in the Chapter and in such hospitals as Bellevue, Polyclinic, New York Nursery and Child's Hospital, Manhattan Eye, Ear and Throat and St. Luke's. Volunteer auxiliaries are in process of formation for ward workers and clinical aides in twelve other health agencies.

Another way in which the Red Cross Health Service helps the Public Health Campaign is by its general publications on health information. I mention only five, but these are representative.

Copies of these and other publications of the health service can be obtained upon request.

(1) The compilation of a directory of Public Health Agencies in New York County. One thousand copies have been distributed and a revised edition of five hundred has been prepared.

A dramatic phase of "Every Child in Elfland," a dental playlet given at Christodora House by the children of Red Cross Child Health Station No. 1.

(2) A directory of dental clinics and dispensaries in New York County, two thousand copies.

(3) Publication in attractive booklet form of a careful survey of nutritional activities in New York County showing the organization and methods of the various nutritional clinics in out-patient departments of hospitals; nutrition classes and hot lunches in public schools; and nutritional activities conducted by organizations such as settlements, churches, and social organizations, two thousand copies, prepared in cooperation with the Child Health Organization of America.

(4) The preparation and publication of a health map of Manhattan showing by symbols the types of health institutions and by colors the special health activities carried on in each institution; some 950 copies of this map have been distributed. They have gone to all hospitals, dispensaries, settlements, public health and social agencies in Manhattan, and also copies of this health map are displayed in every branch library, railroad and ferry station and many department stores on Manhattan. National Headquarters of the American Red Cross and the Atlantic Division have been sent copies of the map at their request.

(5) Publication of a directory of dispensary facilities in New York City, prepared by the Dispensary Development Committee of the United Hospital Fund, two thousand copies.

When the above program support-

ing the work of Public Health Agencies had gotten well under way, the Health Service Committee, after detailed study of four different sections of New York, recommended to the Executive Committee that the Chapter engage in actual administrative health work. This recommendation was approved by the Executive Committee of the Chapter, and on September 30th, 1920, was confirmed by National Headquarters of the American Red Cross. This administrative health work is taking two forms:

(1) The establishment of a Community Health Center to demonstrate the methods and the value of the co-ordination of all health and kindred activities in a defined local area including about one hundred thousand people. The East Harlem section of New York, extending from One Hundred and Fourth to One Hundred and Twenty-Fourth Streets, from Third Avenue to the East River, has been selected and three buildings on One Hundred and Sixteenth Street, in the exact center of the district, have been bought and are being remodeled for the health center building.

It is proposed to bring together into this health center for local administrative purposes, and so far as practicable for operating purposes, all the existing health and family welfare agencies doing work in the district. The buildings are provided and will be operated by the New York County Chapter; needed space with light, heat, telephone and janitor service is given rent free to agencies who are

"A Family Meal," staged in a nutrition health playlet given at Christodora House in March.

Weighing and measuring in as conducted at Red Cross Child Health Station No. 2, Greenwich House, 27 Barrow Street.

invited to cooperate in the health center; each agency, however, retaining its complete autonomy within its particular field. Arrangements have also been made to secure the establishment of such additional health activities in this selected district as will, with those now existing, constitute a fairly complete health program. The health center is controlled by a council, composed of representatives from each agency operating in the center together with a certain number of representative citizens, preferably residents in the district, and a certain number of representatives of the Executive and Health Service Committees of the New York County Chapter, American Red Cross. The executive officer of the health center, who is secretary of the council, has been appointed by the New York County Chapter and approved by the council. The East Harlem Health Center is planned as a national health demonstration. Every facility will be given those who wish to visit the center or learn of its details.

(2) Three Red Cross Child Health Stations in sections of Manhattan where the need is greatest and where the chapter can secure the largest co-operation from some existing agency, such as a school or settlement, have been established. Each station conducts nutrition classes for under-nourished children, dental hygiene and dental clinics. These Red Cross Child Health Stations have been in operation some months. The first was opened on October 25 in co-operation with Christodora House, on the lower East Side; the second was opened on November 14 in cooperation with Greenwich House, on the

lower West Side; and the third is at public school No. 43, Manhattan, One Hundred and Twenty-ninth Street and Amsterdam Avenue. The third station is part of an interesting demonstration being carried on at public school No. 43, to give an effective health service to a typical public school. The demonstration is made possible by the close cooperation of the Bureau of Child Hygiene, Department of Health, Teachers' College and the American Red Cross. In this demonstration the Red Cross provides and conducts dental hygiene and dental clinics in the school building and conducts nutrition classes for the children in cooperation with Teachers' College.

Municipal Cooperation

Finally, the health service is assisting the City Department of Health in three ways at the special request of Commissioner of Health, Royal S. Copeland, M.D.

(1) Tabulation and analysis of statistics of mortality and morbidity from 1916 to 1920, inclusive, for the 224 sanitary areas into which Manhattan is divided for purposes of the Department of Health and the U. S. Census. This work is being done by two clerks paid by the Red Cross, who are given a room at the Health Department. Their work is directed by a special committee of statisticians.

(2) The Health Service of the Chapter has appropriated a sum of money to assist the Health Department in making a demonstration in the immunization from diphtheria of approximately 52,000 public school children by the Schick Test. This has been carried on this spring with the personnel of the Health Department, the Red Cross supplying the salaries and receiving weekly reports on results. A very large number of consents have been secured from the

parents of the children and approximately 30 per cent of the children have been found to be susceptible to diphtheria so that the local chapter of the Red Cross may feel that it has prevented more than fifteen thousand children in New York City by this demonstration from contracting diphtheria, who were found susceptible to it.

(3) The Health Service of the Chapter has opened five dental hygiene clinics in public schools in Manhattan to demonstrate to the Board of Estimate that there should be a dental hygiene clinic in every school in New York City.

This work on vital and sickness statistics; this demonstration of the Schick Test to determine the susceptibility of children to diphtheria; and the placing of dental hygiene clinics in certain public schools were all planned for in the budget of the Health Department. At the last moment the appropriation for these objects were struck out by the Board of Estimate; the Health Commissioner turned to the Red Cross for assistance. National Headquarters gave us a special appropriation to do some of this work and the Junior Red Cross also gave us funds for two of the dental hygiene clinics. The results both in the work and in cementing cordial relations with the Health Department have been most gratifying.

To sum up:

The promotion of health activities in New York County as well as co-operation with existing health agencies are the absorbing interests of our Red Cross Health Service and give this work its peculiar fascination. The New York Nutrition Council is an example of our interest in the promotion of health activities. This Council representing now nearly ninety agencies in and near New York City was formed last fall, and has held twelve meetings with attendance from

Many of these children have for the first time consistent supervision in fundamental health practices.

fifty to three hundred and has greatly stimulated and standardized methods in this most popular subject of malnutrition among children. Our Chapter largely assisted the formation of this new informal Council and has printed its first publication—a valuable bibliography of nutritional subjects.

To illustrate once more our interest in cooperating with health agencies let me say just a word about a demonstration now being carried on to give a health program to pre-school age children in New York. At the suggestion of Dr. Ira S. Wile, the Department of Education and Health, Teachers' College, and the American Red Cross are uniting in making a demonstration group of one thousand children physically ready to enter school in September. During June in eight selected public schools these pre-school age youngsters, about one hundred and twenty-five in each school, are being examined by the Department of Health physician; they then receive mental tests from psychologists from Teachers' College; they have their teeth cleaned by the Red Cross dental hygienists, and it is the job of the Red Cross nurse to see that the necessary follow-up work is done this summer for the removal of physical defects.

While in less highly organized communities it is quite proper and indeed necessary, for the American Red Cross to embark itself on health activities, it seems to me that in the very highly developed communities, such as the largest cities, the plan above outlined seems the most profit-

The children of Christodora House neighborhood, weighing in and having their teeth examined, on Health Rally Day. One thousand fathers, mothers, and children were in attendance.

able kind of Red Cross Health Service.

It will be seen that the entire health program of the New York County Chapter, American Red Cross, then is one of cooperation; that no health activities are undertaken alone; that no Health Service is provided without securing the cooperation of some other organizations, much of this service being undertaken at the special request of other health agencies. To supplement and not supplant the public and private health activities of the city is the motto of this new Red Cross service.

In closing may I share a thought with you? When the records of the Surgeon General's office during the Great War showed that approximately every third man was rejected by the Draft Board because he was physically unfit to fight for his country, a National health emergency had arisen. The answer of your American Red Cross to this National health emergency was the organization and development of its Health Service. With the main features of the Health Service you are quite familiar. The splendid activities of the hundreds of public health nurses throughout this far flung country of ours are well known. Already there are more than four hundred health centers in our Country supported wholly or entirely by Red Cross personnel and funds. You know of Red Cross classes in Home Hygiene, in Home Dietetics, in First Aid and Life Saving. In my paper I have outlined the type of Health Service being developed in some of the larger Chapters. Can we not now catch a vision of what

it will mean for the future of our country and our people when behind all the Public Health Programs of the country there is the swing of our great National American Red Cross?

Compiles Information on Funds for Research

The Research Information Service of the National Research Council has recently compiled information about funds for scientific research. From this compilation it appears that there are hundreds of special funds, trusts, or foundations for the encouragement or support of research, in the mathematical, physical and biological sciences, and their applications in engineering, medicine, agriculture and other useful arts.

So numerous have been the requests to the Research Council for information about sources of research funds, availability of support for specific projects and mode of administration of particular trusts or foundations, that the Research Information Service has created a special file which it is proposed to keep up to date in order to answer the questions of those interested in such funds. Furthermore, in order to give wider publicity to the immediately available information about research funds, the Council has issued a bulletin under the title "Funds Available in 1920 in the United States of America for the Encouragement of Scientific Research."

Inquiries concerning the bulletin or for information should be addressed, National Research Council, Information Service, 1701 Massachusetts Avenue, Washington, D. C.

A Health Center with Emphasis on Health

Public Health Will Be Achieved Only
When It Becomes a Popular Objective

By PHILIP S. PLATT, M.A., C.P.H., DIRECTOR, NEW HAVEN HEALTH CENTER, NEW HAVEN, CONN.

THE day is coming when the well person will take his annual health examination as naturally as he balances his bank book. This day, remote no doubt, will be hastened when health centers become points from which health knowledge, enthusiasm, and inspiration radiate and proper understanding is given to the well or the slightly indisposed person. Whether a conscious or unconscious, "Will to Health" can be stimulated in people may be doubted by many. That it is most difficult, if not impossible, to create such an attitude of mind from a center where, because the treatment of the sick is practised, the major emphasis is necessarily on sickness, is admitted by many who are striving toward the development of a positive ideal of health. The health centers where dispensing of medicine is not practised, where the medical and physical examinations are intended for individuals who are well or only "indisposed," and where briefer health consultations are available at any time, are still very few in number. Among these is the New Haven Health Center.

The New Haven Health Center organization properly coordinates the health workers while preserving the community contacts that mean community interest.

It is definitely aligned on the side of the normal person or the person who is only slightly indisposed. It does not give medical treatment but acts as a listening post or detector of the early beginnings of disease, and then as a clearing house, referring individuals needing medical at-

tention to their own physicians, or if that cannot be done, to the dispensaries and hospitals of the city.

There is also significance in the fact that it is a cooperative effort. The four principal health agencies in the city organized it and support it, namely, the Board of Health, the Visiting Nurse Association, the American Red Cross and the New Haven Medical Association.

In this brief article there is no space for a description of the origin, organization, purpose, activities, and accomplishments of the Health Center, though a part of this information may be gained from the accompanying photographs. Certain it is that the first twelve months just passed afford altogether too short a period to permit an evaluation of the work accomplished.

The district itself is predominantly Italian, a bare third of the twenty-seven thousand residents comprising other nationalities, such as Irish, American, Polish, and Jewish. It is composed of three well defined city wards covering about three hundred and sixty acres and seventy-five city blocks, in the shape of a triangle, and measuring a little less than a mile along the base and a little more than a mile along the perpendicular. Three neighborhood houses, an important boys' club, the Y. W. C. A., six schools, seven churches, and three

Organized in July, 1920, the New Haven Health Center serves a population of 27,000. Over 69,000 health promoting services have been performed by the staff of twenty workers during the first year. No medical treatment is given, but it is a clearing house which promotes health habits.

A prize fighter formerly ran a saloon in these quarters, where infant welfare conferences are now held. In the background, behind the partition, are the medical offices, where physical examinations are made and the prenatal service held. There are five other well-baby conferences in the Health Center district.

parks and playgrounds complete the picture of this heavily congested, old section of the city, now given over to industry, commerce, and habitation.

The activities of the Health Center fall into two groups: those which are definitely attacking disease and those which are endeavoring to conserve health. In the attack upon disease the Health Center is officially delegated by the Health Department with the responsibility for the control of communicable disease. It is caring for the bed-ridden sick through generalized, localized, visiting nurses. The early recognition by means of physical examination of conditions needing medical attention, and the bringing of the individual needing medical care in touch with his doctor or dispensary, is a direct attack upon disease in its earlier stages.

Physical Inventory Urged

The effort to conserve health in the healthy is made through the physical examinations of well people, through readily available health consultations, through well baby conferences and the prenatal clinic, through special health classes, through educational work of health talks, leaflets, posters, lantern slides, and window exhibits. The supervision of the health of the school child by the school nurses, the medical inspection of the children (children absent from school more than three days are medically examined at the Health Center

before being permitted to return) and the far reaching educational work of the school nurses, the dietitian, the dental hygienist, and sanitary inspector are further health constructive measures. The use of prophylactic measures to protect against disease is slowly being accepted by the district. Community interest in health matters is being

aroused through a local advisory council of thirty citizens, residents in the Health Center district, whose advice is sought and freely given on matters concerning community interests or cooperation.

The educational work of the Health Center has been carried on in a variety of ways. Among other interesting novelties has been the use of the automatic attract-o-scope. This was placed in one of our four sidewalk windows. The lantern slides used in this attract-o-scope gets across to the man in the street such striking health messages as the following, which, serially tell the story of the activities of the health center and what it has to offer him:

Are you 100 per cent fit? If not, come inside and find out what to do about it through a medical examination made on appointment, free of charge.

Nobody loves a sick person. The person who is not 100 per cent well owes it to himself and his family to get well. Start right with a yearly medical examination.

One-half of the sickness in this district is preventable. Why not prevent it by (1) Sound living habits; (2) Early recognition of disease; (3) Proper medical and nursing care.

To bring health within the grasp of all. This is the Health Center Motto. Are you doing your share?

Alternating with these captions are attractive colored lantern slides dealing with health subjects. It goes without saying that the attract-o-scope attracts. Its appeal to the

An Italian fruit store was transformed into the reception room of the Health Center. In the rear are the offices of the director and of the supervisor of nurses, and of the sanitary inspector. Through the passage way to the adjoining room may be seen the laboratory.

children is irresistible, and once a nucleus is formed around the windows every passerby stops to see a number of slides.

How Center Is Financed

The financing of the Health Center has been distributed between the organizing agencies in an interesting manner. The Department of Health is contributing at the rate of \$10,700 a year in addition to detailing a staff

of four workers at a cost of \$5,400. The Visiting Nurse Association is detailing a staff of ten at a cost of \$15,120. The American Red Cross has in the past met the cash deficit of the budget, having contributed \$17,400 for a period of a year and three quarters. The budget for next year is \$38,040.

Statistics show inadequately the real work that is done by any health center. Much of the most valuable work that is done cannot be so con-

veniently labelled and counted. However there is some significance in the fact that more than 69,000 health promoting services were performed by the Health Center during the first 12 months of its activity.

It would seem that the time has come for a more aggressive concern with positive health ideals, and that among other agencies the health center has an unprecedented opportunity to emphasize this constructive point of view.

Health Stunts to Interest Everyone

BY LEONHARD FELIX FULD, LL.M., PH.D., NEW YORK CITY

FACULTIES unused become faculties atrophied. We are fortunate if we are able to realize our objectives. We cannot rightly expect to exceed them if we fall short of consecutive, consistent effort toward a given goal. This is true of mental achievement, but it is especially true in matters pertaining to health. If the body is to be a serviceable instrument, it must be trained to control, response, and steadiness. The use of the daily health stunt, particularly if it can be embodied in a game or utilized in the spirit of fun, is of the greatest value. Here are a few old exercises put to new uses.

No. 1. The Sit Up and Stand Up.—Are you going to the beach today? The sea breeze will refresh you. What will you do at the beach? Take a dip in the surf and loaf on the sand? Get some lasting benefit from your day at the seashore. Practice a health stunt.

Your bathing suit gives you a sense of freedom which you cannot enjoy in your street clothes. The soft sands are admirably suited for exer-

Fig. 2. Second position in the "Sit up and stand up" exercise. This is a waist-reducing stunt.

cise. How do you get up in the morning? Do you make a football of yourself before you roll out of bed like

a sailor? Lie flat on your back on the sand with legs extended in front of you. (Fig. 1). Fold your arms across your chest. Bend at the hips and sit up. With arms still folded stand up on the sand (Fig. 2). Do you find this a little difficult? Why can you not do what most children can do? Has long continued sitting robbed your abdominal muscles of strength? Is your waist no longer the shortest circumference of your body next to your neck? This stunt will reduce your waist. It will cause your unsightly paunch to disappear. It relieves many of their constipation. Practice the sit-up and stand up on the sand with your friends. Who can do it most gracefully, most rapidly, most perfectly? Perform this health stunt every morning upon arising from bed. Get lasting benefit from your day at the seashore and note the improvement in your general health. Practice a health stunt daily.

No. 2. The Yellow Dog.—Did you practice the sit up and stand up on the sand when you last went to the seashore? Do you practise this movement every morning in bed before

Fig. 1. The daily practice of the "Sit up and stand up" stunt is progressively beneficial.

Fig. 3. When you can walk like a dog with facility, you will enjoy it. Your friends will enjoy it, too.

Fig. 4. This exercise will fill up the hollows in your chest

Fig. 5. Make your muscles serve you instantly, completely, unhesitatingly, unflinchingly which means perfect coordination

arising? Are you deriving benefit from the sit up and stand up? Are you planning to go to the beach again? Will you learn another health stunt? Try the yellow dog. Get down on all fours on the sand. Make yourself as long as you can. Hold your head, your shoulders, your hips high (Fig. 3). Be a proud dog. You can do everything a dog can except wagging a tail. Walk on the sand on your hands and toes like a dog. Do you know how a dog walks? Watch and learn. Which of the four legs comes forward first? Which next? Which next? Which last? Walk slowly at first. Practice the dog's ways. When you can walk like a dog with facility, trot along more rapidly and enjoy it. Your friends on the beach will enjoy it too. Are you getting winded? Learn to breathe properly. Breathe rhythmically, regularly and deeply. Are your arms getting tired? Are your shoulders getting too heavy for your arms? Hold up your shoulders and develop your arms. Try the Yellow Dog with your friends. Who can walk furthest? Who fastest? Who can best imitate a dog? Don't lie lazily on the sand all day. Get physical benefit from your trip to the beach. Learn a health stunt. Try the Yellow Dog.

Transfers the Load

No. 3. The Crab.—Do you carry a knapsack on your back? Not one like soldiers carry, but one of flesh and blood? Most of us office-workers carry one. When you buy a suit of clothes does the salesperson smile engagingly to you and say: "I'll get the tailor to make this fit better around the shoulders." You know what that means! Would you like to transfer that knapsack from your back to your chest? Plenty of room there. Fill up the hollows of your chest. Try the crab on the beach to-

day. Bend your knees as if you wished to sit on your heels. Now bend backward until your hands touch the floor (Fig. 4). Arch your back and hold your head up.

This is the crab. Walk slowly and stately on the sand on all fours in this position. Who of your friends can walk the crab most rapidly? Breathe deeply and regularly. Walk the crab each morning from your bedroom to the bathroom. Move that knapsack from your back to your chest. Isn't it more comfortable?

A Test of Sobriety

No. 4. The Fishhawk.—Have you ever walked the ties of a railroad track? Were you a little unsteady? Did you ever walk a trestle? A bit shaky?

Do you know the old police test of sobriety? It was the ability to walk a crack in the floor. Can you walk the crack? You are sober, why do

you find it so hard to accomplish? Have you been inactive so long that you are muscle-bound?

Develop your balancing ability. It will come in useful. It may enable you to save your life. Practise the fishhawk on the sand. Kneel on one knee. Keep your other leg and both your arms off the sand. Place a handkerchief on the sand in front of your bent knee. Balancing yourself on your bent knee, swoop down like a fishhawk and pick up the handkerchief from the sand with your teeth (Fig. 5). It is fun. It is good for you. It is useful. Make your muscles serve you instantly, completely, unhesitatingly, unflinchingly. Practice the fishhawk every morning on arising. Pick up at least one article of your clothing in this manner each morning. Strive for perfect coordination of nerve and muscle. Are you sober? Then walk the crack. The fishhawk will help you.

Drug Addict Camp for New York

International Film Service Co., Inc.

The use of Pelham Bay Naval Training Station has been secured by the City of New York as a camp for drug addicts. The station now has only about fifteen hundred naval men there. Arrangements can be made for the care of 14,500 drug addicts. Ideal conditions prevail for the handling of such cases under the staff of physicians, nurses, and attendants in charge of the camp.

International Training at Bedford College

By KATHERINE OLMSTED, DIRECTOR OF PUBLIC HEALTH NURSING, LEAGUE OF RED CROSS SOCIETIES, GENEVA, SWITZERLAND

ANOTHER International Course in Public Health Nursing will be given in London. The League of Red Cross Societies has recently completed arrangements with Bedford College for Women, University of London, to give a nine months' course in Public Health Nursing for International Students to begin October 6, 1921.

This course has been established in order to seek out in all countries the nurses who by reason of intelligence and training may become leaders in the evolution of nursing ideals in their own country. These women will receive the necessary knowledge and inspiration, so that, upon their return, they may become pioneers in Public Health Nursing in countries that service is just being initiated. In countries where nursing is well developed, by reason of their greater knowledge, they will strengthen the world-wide nursing bond.

During the past year nineteen students from eighteen countries have taken a similar course at King's College for Women, London, under the auspices of the League of Red Cross Societies. These students will shortly return to their countries as well trained leaders and staunch advocates of better and more efficient public health nursing services.

Scholarships are being given by the Red Cross Societies of many different countries so as to enable their nurses to attend. The Red Cross Societies of Japan, New Zealand, China, Great Britain, and Bulgaria have already signified their intention of sending nurses.

The amount of each scholarship is 250 pounds sterling which will cover tuition, laboratory fees, and special fees to the college, board, residence, books, laundry, necessary transportation and incidental expenses connected with the course. Travelling expenses to and from London must be furnished in addition to the above sum.

Many inquiries are being received from nurses who wish to attend the course at their own personal expense. Nurses have recently inquired from Poland, Denmark, Mexico, England, Switzerland, and Canada.

The following qualification are laid down by Bedford College for Women

and by the Department of Nursing, League of Red Cross Societies:

Age.—23 to 40 years of age.

Education.—Evidence must be produced showing continuous education up to the age of 18 years.

Training.—The student must possess a diploma or certificate as regulated by the highest nursing standards of the country which she represents.

Health.—A medical certificate of general good health must be produced.

Reference.—Should be given in evidence of good character and efficiency. Red Cross Societies selecting students must pay particular attention to the necessity for unusual intelligence to enable them to profit by a course which is necessarily intensive.

Language.—The students must be sufficiently familiar with the English language to follow lectures and take notes.

A Form of Application must be filled in and returned to the Director of the Department of Nursing of the League of Red Cross Societies.

Session.—The College Session opens in October and closes in July.

Holidays.—Short holidays will be allowed at Christmas and at Easter during which time the student will have ample opportunity to visit the points of interest in and about London, under the direction of the League representative.

Certificate.—At the end of the session a final examination will be held

and, if successfully passed, will entitle the student to a certificate.

Residence.—Comfortable living arrangements have been made by the League of Red Cross Societies for all students attending the course at a very nice family hotel near the College. The syllabus of the course follows:

Theoretical Work

1. *Hygiene and public health.*—Tuesday and Friday, 9-10 (60 hours).

1. Personal Hygiene: Importance of cleanliness, exercise, sleep, etc.

2. Community Hygiene. Water supply, sewerage, milk supply, housing, sanitation, etc.

3. School Hygiene: Physical conditions affecting health, indications of ill health and defects, effects of fatigue, employment, etc. Recreation: care of defective, retarded, abnormal children, schoolroom sanitation.

4. Hygiene of special senses: Eye, ear, nose, throat structure, mechanism, preservation, treatment dangers.

5. Prevention of communicable disease: Micro-organisms in relation to disease—modes of attack, resistance of body, disinfection, etc.

6. Oral hygiene: Importance of care of teeth.

7. Maternity, Infant and Child Care:

a. Principles and organization of Child Welfare work; growth and de-

A nine months intensive course is provided for international students of nursing at Bedford College, University of London

The course is highly intensive and offers unusual opportunities for such matriculates as are intelligent and have the necessary background to take advantage of its opportunities

velopment of child, mentally and physically.

b. Ante-natal Hygiene: Cause of mortality in infancy; directions for maintenance of health.

c. Care of Mother and Infant: Symptoms of ill health; common infant ailments, treatment and care. General care of infant, feeding, bathing, clothing, etc.

d. Food Values, Dietetics, Nutrition:

d1. Principles of Diet.

d2. Hospital Dietetics.

II. *Teaching of Hygiene*.—Five lectures in third term (time to be arranged).

1. Theory and practice of education.

2. Practice in Teaching: Health talks to mothers; teaching health to school children.

3. Value of Visual Education: Illustration of health facts, publicity and exhibit methods.

III. *Elementary bacteriology*.—Five lectures, followed by practical work, in first term, Tuesday, 2-4.

IV. *Elementary psychology*.—Including infant psychology), 30 lectures, Tuesday, 10-11.

V. *Modern industrial conditions*.—(Including industrial problems). Thursday, 10-11.*

*VI. *Social Administration*.—Thursday, 11-12, followed by a discussion class, 12-1.

Practical Work

The practical work will cover two and one-half days a week.

*Attendance in the second and third terms, when the lectures will be on English conditions and local government, will be optional.

I. *Attendance* at child welfare centers, day nurseries and children's hospitals, enabling students to study physical conditions of large numbers of infants and children, helping generally in all activities of clinic, such as weighing, filing records and home visiting. One day weekly.

II. *Attendance* at a tuberculosis dispensary.

III. *Experience* with district nursing associations in city district in order to get some insight into practical bedside nursing work in the homes.

IV. *Experience* in School Hygiene work—physical examination of children, home visiting, cleansing stations, schools for mentally and physically defective children.

V. *About thirty excursions* to places of interest in connection with hygiene and public health course.

Public Health Subjects

Classes in public health nursing subjects will be given or arranged by a representative of the League of Red Cross Societies with the approval and cooperation of the Principal of Bedford College for Women.

I. *History of nursing*.

II. *Principles of public health nursing*.

III. *Development of health visiting and public health nursing in various countries*.

IV. *The responsibilities and duties of the public health nurse* in relation to: Schools, factories, homes, hospitals, out-patient clinics and dispensaries, general public health and sanitation.

V. *Development, organization and administration of:* (a) Visiting or district nursing, (b) child welfare nursing, (c) maternity and infant nursing, (d) rural and small town nursing, (e) clinics and health centers—traveling or permanent, (f) open-air schools.

VI. *Vital statistics*.—Use and value to public health nurse.

VII. *Records and reports*.—Value and method.

VIII. *Ways and methods of teaching:* (1) Home care of sick, (2) first aid, (3) school hygiene.

IX. *Supplementary lectures:* (1) Red Cross activities, (2) venereal disease, (3) tuberculosis nursing, (4) obstetrics, etc., nursing.

Excursions Arranged

The students will be personally conducted to the following centers or activities:

I. *Social:* Charity Organization Society Office; Schools: Elementary, secondary, kindergarten; district nursing association; settlements.

II. *Child Welfare:* Crèche work, child welfare centers, maternity, hospitals, nursing schools, home nursing, school clinics and inspection.

III. *General:* Hospitals, training schools, nurses' hotels and clubs, college of nursing, and others to be selected later.

The scholarship includes tuition, laboratory fees, special fees to the college, board, residence, books, laundry, necessary transportation and incidental expense connected with the course.

Cleanliness is the only real disinfectant. No epidemic can resist thorough cleanliness and fresh air.—Flour-ence Nightingale.

The New "Round-Up" on the Old "Range"

Improvement Marks the Matters that Occupy the Interest and Attention

BY WILSON ADAMS RUSSELL, M.D., COUNTY HEALTH OFFICER AND SCHOOL PHYSICIAN IN BIG HORN COUNTY, HARDIN, MONT.

FIFTY years ago in the southeastern part of Montana the American Indian chased the bison up and down the long valleys, across the level benches and among the foothills of the Rocky Mountains.

With the onward march of civilization, the bison became extinct, the Indians were rounded up and placed upon reservations and the vast prairies were covered with immense herds of cattle. In the spring of the year the cowboys went out with their lariats, lassoed the calves and branded them, that they might keep a careful record of the owner and breed.

A law was passed in the early days forbidding anyone to turn loose on the range, anything but pure bred and healthy sires, and, as a result, the white-faced Hereford stock of Montana is known all over the United States.

The onward march of civilization brought about still another change. The rivers were turned out of their usual channels and made to irrigate the semi-arid valleys and the modern method of dry land farming turned the bench lands into valuable wheat farms.

Child Care Stimulated

This brought into the West many young people with the view of making homes for themselves, and now the great question before the people of our state is not so much the question of pure bred cattle, but whether we have healthy and robust children. People are coming to believe that it is more important to give the same intelligent, scientific care and attention to growing children that they have been compelled by law to give their cattle, but no law has yet been passed which insures healthy parentage to the children.

For the past four years, by the co-operation of the county commissioners and school boards of Big Horn County, there has been carried on a campaign for better health among the children and to stimulate the parents to greater interest in their physical condition.

After three years we are beginning to see the results, especially in the

The boy on the left of the picture is a graduate of the malnutrition class, having gained twenty pounds during a period of six months.

death rates. In Big Horn County, with a population of about seven thousand, in 1917 four babies died from preventable bowel trouble and one case from typhoid fever. In the three years—from January, 1918, to January, 1921—but one baby has died from preventable bowel trouble and there has been one death from typhoid fever.

One of the striking results is the improved condition of the rural school buildings. When this work began, there was scarcely a sanitary boys' toilet in the country, 62 per cent of the schools were without water and it was impossible to get 25 per cent of the parents to attend the meetings and discuss the condition of their children.

In the campaign just closed, there were only two toilets in the county which brought the severe condemnation of the sanitary officer, virtually every school is supplied with water where it is possible to get it, and 80 per cent of the parents were present to watch the examination of the children and discuss their condition. In one school, forty-five miles from a

railroad, every parent was present at the examination of the children.

Big Horn county has been organized for only eight years, but all the thirty-five schools visited last year were good frame buildings, with the exception of five, which were log buildings but well built and lighted.

Defective teeth have improved from 54 to 31 per cent, and throats needing operations from 15 to 6 per cent. Last year more than 40 per cent of those having defective eyesight were fitted with glasses and as a result of such correction two children were almost immediately advanced two grades.

The success of the health work in the schools and communities depends upon two factors of equal importance. First, the attitude of the teacher and his ability and energy in putting the lessons over. Second, the intelligence of the community and its distance from town and financial condition.

Results Achieved

At Kirby, Mont., two teachers, Mr. Millard Underwood and Miss Rose Smith, have brought about a remarkable result. Six pupils, four girls and two boys, ranging from eleven to fourteen years of age, have developed an eight inch chest expansion in six months practice and one boy who was fifteen pounds underweight last September, has gained twenty pounds, largely by drinking milk.

In this particular school, physical culture has become one of the big things in the curriculum. The girls wear bloomers to school, chin the bar (in which feat they excel the boys), play leap-frog, and engage in all the games and sports the same as the boys. As a result, not a finer bunch of boys and girls physically can be found in the Northwest.

When the report came into my citice with reference to these eight-inch chest expansions, the county superintendent, Miss Fay Alderson and the author, drove sixty miles to verify the statements.

The County Unit Board of Carbon County, our neighboring county on the west, asked me to carry on a similar campaign for them the past

Six children with chest expansion of eight inches, showing the effect of a well planned health regimen.

year, and I was glad to accept, as the topography and social and economic conditions of that county are different from our own. The lowest point is three thousand feet above sea level and the highest, 12,950 feet. One school is located at an altitude of six thousand feet, but as there was little snow last winter, we made the trip of more than two thousand miles in a car during December and January, examining 1,992 children.

Carbon county is very mountainous, being cut into numerous deep narrow canyons, in some of which are found immense coal mines, worked by people of many different nationalities.

In spite of the newness of the work, which handicapped the teachers somewhat, the results already accomplished prove that the seed was sown on fertile ground and will bring forth abundant harvest. One teacher has seen that every possible defect in her pupils has been corrected.

Mary Roberts Rinehart, speaking of Glacier Park, says, "Go, ride in the Rocky mountains and save your soul." A similar remark might be made in reference to the schools of our country. If you wish to know how extensive is our system of education and how far and upwards the long arm of our paternal government reaches, go, ride in the mountains of Montana, and you will appreciate as never before, the watchful care of our Government over the coming generation.

Although many schools are located in almost inaccessible places, and

miles from a railroad, still these children have a nine months school and a physical examination the same as those who live in the more thickly settled districts.

In Carbon County 43 per cent of the children had defective teeth as against 31 per cent in Big Horn County, where the work has been done for three years. A striking peculiarity in reference to the teeth was the fact that all the nationalities ranked about the same with the exception of the Finnish race, and in one school of 90 Finnish children, 70 per cent had bad teeth. The teeth of these children were broken off, presenting a saw-tooth appearance. One could almost tell a Finnish child by the condition of his teeth. They were also fleshy and over weight, and we were told that as babies they were given a great deal of sweet cake and coffee.

The number of mouth breathers was large, being 22 per cent. In one school of fourteen children, 9 were mouth breathers, and all slept with their windows closed.

Having been much interested the past two years in the subject of goiters, especially with reference to the effect upon them of the altitude and water supply, I made a careful survey this year in both counties.

In Carbon County, which is more mountainous and of higher altitude than Big Horn, 30 per cent of the children had goiters. In Big Horn County, which is lower and less mountainous, the goiters diminished to 17 per cent, while in the Hardin school district of four thousand square miles, occupying the lowest and most level portion of Big Horn County, the goiters diminished to 11 per cent. The conclusion reached is that those children living in the canyons close to the mountains, have more goiters than those living elsewhere.

Poverty and Malnutrition

Of all the children examined this year, 8 per cent were suffering from malnutrition. Except in certain instances, these were all between the ages of 11 and 15. It must be remembered that people living in this new country are in many instances poor, and in trying to make homes for themselves, the boys and girls just coming into maturity, do a man's work and undergo great privation, which perhaps accounts for the cases of malnutrition found in the adolescent period.

Upon inquiry, we found that nineteen out of twenty of the malnutrition cases disliked milk, which leads me to

suggest that more attention be paid to the old cow as a big factor in the up-building of the race.

In this survey of two counties which cover an area larger than the state of New Jersey, we found in a mining town the very unusual condition of 25 per cent of the children in the first grade suffering from malnutrition. These children represented either Scotch-Irish, Slav, or Austrian people. When children of these same nationalities were examined in the third and fourth grades at the ages of ten and twelve years, they were up in weight but were from two to six inches under height.

In discussing this condition with the teachers and business men, the explanation was that the child up to the age of six or seven was dependent upon the mother for food and care and received no milk. In fact, during my stay in this community I only saw two milk cows and no milk wagons. These children also slept with the windows closed.

After the age of six or seven, the child rustled for himself and brought himself up in weight, but, like the stunted calf on the farm, was not able to overcome the handicap of a bad start in life and could not bring himself up in height. It is reported that these parents formerly gave their children from one to five years of age, beer and wine to drink, which may account somewhat for the conditions found.

In contrast to this, only a few miles from here we found an American girl sixteen years of age, living out in the

Girls playing leap frog at Kirby, Mont.

open with plenty of fresh air and milk, who was 6 feet 1½ inches tall and weighed 210 pounds.

While it has been impossible to get reports from all the teachers in the two counties, those received show that one child out of every six examined

between September, 1920, and February 8, 1921, has been to see either the dentist, a throat specialist, or has gained enough in weight to place him outside the malnutrition class.

While we have not progressed far enough yet in the care of children to

pass laws assuring them pure blooded and healthy sires, as we did for our cattle, still, by means of the yearly "round-up" we are correcting their physical defects and nearing the goal which we reached in the care of our cattle years ago.

How the Public Health Nurse Gets There

COMMUNICATION is perhaps the most important factor that enters into present-day civilization; in fact, many students of social conditions hold that the chief points of contrast between modern and

comparatively fixed position of primitive peoples. Without free interchange, the habits of a people become firmly established and invention does not suggest new and better ways of doing things without the dynamic influence of multiple contacts. Whatever the principle is that energizes thought, it is set going through social stimuli. Robinson Crusoe is the only individual who ever accomplished much in isolation, and he carried his ideas and materials with him. In groups of minds that react to the same interests is developed what we designate as the public.

In the mountainous districts of Kentucky, where the people never get beyond the points of a single county, the public is small, the community spirit apathetic, and the interests of the people circumscribed. It is under such conditions that folk lore is conserved, archaic forms of speech remain current, and practices obtain that have been long outgrown elsewhere. The larger reading public who break down physical limitations and communicate with the whole outside world is more plastic, less fixed, and makes up the personnel of the advance guard of civilization.

The social progress of a community, then, is in a high degree related to its accessibility. Social workers, who

are the missionaries of social progress, must blaze new trails, and open new channels of communication so that isolated communities are isolated no longer, but become incorporated into the larger public.

The public health nurse walks through the city streets. Her cases are usually assigned with a view to keeping them within walking distance.

primitive peoples are to be explained in terms of the relative mobility and freedom of contact that obtain now as compared with the isolation and

A day in the "rickshaws" of Japan.

No small part of the difficulties of the work of the public health nurse consists in covering the ground between the health center and her widely separated charges. The good roads movement becomes a part of the better health movement because it facilitates communication. Complete medical service is a mobile thing and can be carried anywhere if the road is open.

The National Organization for Public Health Nursing has furnished us with pictures which bring out this phase of the public health nursing problem. Even in the city much time and energy are expended in getting about. Usually assignments are restricted so that the nurse may walk from place to place. Her faithful Ford carries her to more remote corners. Public health nurses are as essential in far away Lapland as they are in countries where neighborhoods

These public health nurses in Lapland have difficulties all their own but undertake them in a spirit of adventure.

This marks a particularly lonely spot covered by an American Red Cross nurse on snow shoes, making a trip to a country home in New York.

are not so isolated and where less travel is necessary and involves less hardship, and transportation difficulties do not hamper the public health nurse. Indeed, in a population where the simplified diet is drawn from stores in which fresh foods are lacking, public health problems may become very urgent. Deficiency in dietaries is reflected in the retarded growth of the children, the frequency of psychoses, and other special problems; but the chief problem of the public health nurse in such a community is how to get about and properly and regularly supervise her charges.

Wherever public health nursing is carried, one of the chief requirements in preliminary training is that the nurse in charge familiarize herself with the mental habits and general customs of the people. It is for this reason that sociologic courses are now being given to missionaries in foreign countries. Initial courses of this kind open up ways of immediate contact that simplify the work and enable the nurse to enter the local life and quickly gain the confidence of the people. This is particularly essential in districts where what is accomplished in the way of hygiene, modifications of dietary, etc., are difficult to carry out unless many concessions are made to previous habit and custom.

A recent report from one public health nurse in the South reports that to cover her district she travels twenty-five miles on Monday, five and a half miles on Tuesday, nine miles on Wednesday, and thirteen miles on Thursday. Transportation, she says, is very hard for her in her work. Sometimes the boats make the trip and sometimes they don't, and sometimes roads are impassable. Health prob-

lems among the negroes of the South are complex. Housing is poor. Child labor laws do not affect the children

The transportation of the nurse is accomplished under favorable conditions in hot Louisiana.

in the cotton fields, where they work side by side with adults. Public health problems present peculiar

phases in the agricultural portions of the cotton districts. Cotton growing, it is held, cannot be accomplished profitably unless the whole family works in the fields, and father, mother, and little children work side by side throughout the day; the home is neglected, meals are hastily and badly prepared, and perhaps not sufficiently varied. Fatigue, unfavorable living conditions, and poor diet constitute a formidable triad, and the public health nurse who shows these people how to make the best of such conditions is doing an important work. Health work takes on another aspect in the cotton manufacturing industry. In this case, to general unhygienic condition of dwellings is added the factor of overcrowding. The health hazards vary from community to community, but the health nurse goes everywhere to reduce the debilitating influences and to inculcate better practices.

Apparently the public health nurse of Japan has a more picturesque field and an easier means of locomotion. Louisiana has developed a highly mobile health service. Health trains, laboratories on wheels, traveling clinical units, find their parallel in the public health nurse who is transported by automobile.

The nurse in the Northwest is again dependent upon her own powers of endurance to get her across the stretches that lie between one client and another. It is one thing to develop a health center in a city and quite another to do effectual health extension work for isolated districts.

Transportation offers few difficulties to these nurses en route for service in Europe.

Research to Replace Rule-of-Thumb Epidemiology

THE realization for the first time that man has never completely eradicated any disease may come as a distinct shock to many hitherto optimistic health workers. To be sure, a given disease may have disappeared from a certain locale and sometimes it has appeared pretty certain that this came about as the result of definite sanitary measures, but always the disease exists somewhere else and is therefore liable to recur. We have the same epidemics now as in the Middle Ages, some of them, notably influenza, making quite as disastrous incursions as in that remote period. Plague is widely distributed; smallpox in modified form is present in practically the entire Carribean littoral; typhus prevails in many countries; tuberculosis continues to scourge mankind; the venereal infections flourish; cholera and typhoid exist in many nations; malaria is far from being conquered. In spite of the hope of many sanitary crusaders that at last man was putting "death beneath his feet," the communicable diseases continue.

The fact remains, however,—and it is here that encouragement should be derived—that it is only recently that man has acquired any really definite knowledge of epidemiology and that the world eradication of disease has just begun. It must be admitted in all honesty, that with regard to most diseases our knowledge of their modes of continuance and spread is exceedingly sketchy,

and, while we must continue to combat the infections with the weapons at our hand, we cannot make any permanent progress until research has added to our armamentarium. In other words, successful disease warfare requires instruments of precision and an accurately organized effort.

In the case of yellow fever, these prerequisites have been supplied. Carter's discovery of the extrinsic period of the infection, Reed's immortal confirmation of Finlay's theory, the amplification of its application by Gorgas and White, the creation of the Rockefeller Yellow Fever Institute, the epoch-making demonstration at Panama, the substitution of steam for sails, and Noguchi's studies have combined to draw the fangs of the jaundiced scourge of the Antilles. In less than a quarter of a century, the greatest enemy of tropical and sub-tropical life and commerce has been stamped out in its great endemic centers. It has been driven to its birthplace, Yucatan, where it is in a fair way to be forever conquered. This is possible because yellow fever warfare has been reduced to a single definite method, the destruction of the immature *Stegomyia*. Quarantine, isolation of the patient in the infectious stage, and the use of Noguchi's vaccines and sera are all secondary to the basic principle of the lowering of the *Stegomyia* index.

Plague eradication has been reduced to a certain fairly satisfactory formula, but a method of accurate, certain rodent destruction has still to be evolved. The wiping out of enzoötic foci, particularly where the disease is widespread among rural rodents, awaits research.

Tuberculosis control is in a far worse plight. Propagandists infest the land, spreading half-truth shibboleths and teaching doctrines which are unsupported by scientific evidence. Vast sums which could more profitably be expended in studying the disease are being utilized in carrying on a warfare against a pestilence of whose epidemiology we are still relatively ignorant.

Our situation in regard to influenza is even more humiliating. The recent epidemics of this disease spread unhampered exactly as in the Middle Ages, the only difference being an augmentation of speed induced by modern transportation facilities.

What do we really know about the epidemiology of such common diseases as mumps, measles, scarlet fever, and whooping cough? How is smallpox spread? How long are meningococcus carriers virulent? How much is there really to droplet infection, sputum interchange by mess-gear and overcrowding? What is our proved knowledge of the effects of atmospheric condition on disease spread? Just what is the rôle of over-

crowding, non-infected filth, and fatigue in the causation of the communicable infections!

These and a hundred similar questions which the honest sanitarian must ask himself daily indicate the need of intensive epidemiological research. The cry hitherto has been for sanitarians to do things, it being forgotten by the impatient taxpayer that empirical hygienic measures based on insufficient scientific proof, are usually the most expensive and the least efficient. The time has come for sanitarians to take stock, to discard rule-of-thumb methods and to place public health administration on a sound scientific basis.

A Note Concerning the World Diffusion of Plague

SANITARY officers who are interested in the world spread of disease cannot but be made apprehensive by the present plague situation. Prior to the war, bubonic plague had established residual foci in China, India, the West Coast of Africa, and in the rural districts of central California. These acted as perpetuating reservoirs from which plague flowed out from time to time to gain a foothold in new territory, producing first acute epizootics and afterwards acute epidemics. If there was a concentrated rodent population and rats had free access to human habitations, the epidemic, in the absence of intelligent control operations, was large in proportion to the population. If, on the other hand, there was a sparseness of rodent or human population, or if human beings dwelt for the most part in a rat-free environment, only a few sporadic human cases occurred. If the city rat lived in fairly close proximity to the suburban and rural wild rodent, plague would be passed to the latter with a gradual lowering of virulence, the production of chronic plague, and the establishment of residual focus.

While the experiences of the Public Health Service in California demonstrated how well nigh impossible is the eradication of such a focus, they also showed the practicability of delimiting the infected area and of preventing the spread of the disease into urban centers.

Just prior to the war with Germany, plague was reported in Venezuela, Brazil, Chile, Ecuador, Peru, Cuba, Louisiana, and California, in the Western Hemisphere; in the Azores and Russia; in Turkey, Arabia, Persia, Ceylon, India, Siam, Indo-China, Dutch East Indies, the Straits Settlements, the Philippines, China and Japan; in Egypt, Morocco, Tripoli, Senegal, British East Africa, German East Africa, Zanzibar, and Mauritius; in Australia, Hawaii and New Caledonia.

In other words, on June 30, 1914, plague belted the world.

Then submarines and raiders began to infect the seas; in a moment the shipping of the world was diverted to the carriage of munitions; steamships moved in convoys; international maritime schedules were rearranged, and many hitherto busy ports were temporarily abandoned; the fleets of the globe were taken over by the Allies; production fell off enormously; world commerce underwent a complete metamorphosis. In spite of this tremendous change, the Armistice found plague distributed practically as it was at the beginning of the war five years before. In other words, while commerce had not spread the disease, civilization had been too busy in its fight for self-preservation to wage warfare against pestilence.

In the period of readjustment which succeeded, the nations found themselves impoverished and for the most part that condition still prevails. People who are struggling for the barest necessities of life cannot appreciate the necessity for plague eradication, therefore plague has had seven years in which to dig itself in and to establish chronic enzoötic foci.

Just now ship movement is still below the pre-war average rate. World commerce will keep pace with the return of prosperity and correspondingly the potentialities of plague diffusion will increase. If plague is actively combated now while shipping is slack, those potentialities will not be realized. Plague can be more cheaply fought now than later and future losses from disastrous quarantine may be avoided.

Some international agency should at once commence an organized campaign against plague. The world menace of the disease should be signaled to the nations and infected ports should be stimulated and assisted to the end that plague repressive measures be immediately instituted. What has been done in stamping out yellow fever indicates how successful such movement could be. The energetic prosecution of a world wide anti-plague campaign is today the crying sanitary need.

Attitude of the Public Toward Civilian Rehabilitation

THE public feeling toward rehabilitation of physical handicapped civilians, on a broad scale, is one of good will. Opinion about the matter, however, being based on particular experiences, is not uniform. Those who are not concerned directly with the work have only the information or impressions they may have gathered about soldier rehabilitation work, the rela-

tionship of which to the civilian problem they can but surmise—with the use for comparison perhaps of one or two cases known to relief societies, or cases of beggars. Doctors, industrial managers, and teachers appreciate the many and varied conditions which would need to be changed before much could be accomplished for the physically handicapped as a group, one often not realizing how much the others are doing to improve conditions.

Those who are convinced of the value of rehabilitation work are the representatives of the Federal Board for Vocational Education, Red Cross workers and occupational therapists, who have been dealing with disabled soldiers, officials engaged in administering workmen's compensation laws, the personnel of public and private bureaus of rehabilitation, and many social workers and medical men who have seen its possibilities with the individual and also the shortcomings of the present discontinuous treatment of the civilian handicapped. What principles or practices they have in common, as a basis for their belief in rehabilitation, have not been discussed to any extent. It is from their experiences that policies of local communities and of the National government may be expected to be derived.

The introductory statement of the problem of rehabilitation made by Mr. William T. Cross in the March issue is continued with the present number. The problem is outlined as the author expressed it, "with no particular faith in administrative machinery as such, or in new names, but with a conviction that the greatest number of disabled persons will be reestablished in the next ten years if the nature of physical handicap and the processes of rehabilitation are more fully investigated; and that the problem may be soluble through coordinating the work of public and voluntary agencies."

Estimated Results of One Life Saving Campaign

GOOD health pays. This is the conclusion arrived at by a large business corporation to whom the saving of lives means a saving of dollars and cents and an increase in dividends. The results of a systematic campaign instituted in 1910 to lengthen the lives of its industrial policyholders, whose mortality had been higher than that of the general population, is evaluated in a recent publication of the Metropolitan Life Insurance Company entitled "Lengthening Life Through Insurance Health Work." By means of a thorough health educational campaign, an extensive visiting nurse service, an industrial service bureau, and practical cooperation with state

and local health officials, the improvement in industrial mortality in 1920 over 1911 has effected a saving of 38,000 lives, which in dollars and cents represents a saving of \$7,530,000 in death claims. Compared with the improvement in mortality rates in the country as a whole, the company shows an even greater saving of 17,800 lives, the equivalent of \$3,451,000 in death claims.

Analysis of the mortality records of the Metropolitan industrial policyholders and of the United States Registration Area reveals the fact that the decline from tuberculosis was three times greater in the former group. The downward tendency of the death rates of communicable diseases among children, typhoid fever, and diseases of the puerperal state was in every case greater among the industrial policyholders than in the Registration Area. An important observation is the distinct decline in the death rates of organic heart diseases and cancer among the industrial group, in contrast with a steady increase shown in these death rates in the general population.

The Framingham experiment, through its extensive efforts resulted in a decline in the tuberculosis death rate from 122 per 100,000 in the period 1907 to 1916, to 65 per 100,000 in 1920, a reduction of nearly one half.

The Metropolitan Life Insurance Company has amply demonstrated that "public health is purchasable," and that "a community can have as much health as it is willing to pay for."

The General Need of Placing a Quietus on Noise

NEEDLESS noise—how often all noise seems to be needless! says *The Modern Hospital* in commending the initiative of the personnel of a Cleveland hospital Society for the Prevention of Needless Noise, as a "blessed campaign" which should be carried well beyond the bounds of institutions for the care of the sick, whose populations may be regarded as sensitized to irritating noises until all noise seems needless.

"Many noises incidental to city life are easily preventable," say the June issue of *Better Health* in an editorial on "Noise and Health"; and a community that regards "health as its greatest asset" will undertake as a measure of preventive medicine the suppression of such noises as the clange of street car gongs, the screeching of whistles, the rattle of heavily laden trucks over badly paved streets, along with the deafening yell of street vendors and newsboys.

Nor is the beneficence of comparative silence a mere matter of sick relief. There is a distinct demand in several cities for the location of schools in the outskirts, where children may be trained

in surroundings where sounds supply something that approaches natural rhythms, it being evident that an environment which entails the bombardment of the senses by incessant din tends to disorganize the developing mind.

The contribution on the subject incidental to the report published in this issue of *THE NATION'S HEALTH*, made by Frank B. Gilbreth, chairman of the International Committee for the Elimination of Unnecessary Fatigue, before the convention of the Society of Industrial Engineers assigns to needless noises a highly important proportion of responsibility for unnecessary fatigue in industry. Two of the most significant contributions to this meeting, made by foreign members, had to do with the elimination of noise, and the suggestion was carried that the elimination of noise be made the subject for general attention on Fatigue Elimination Day, set by the Society of Industrial Engineers for the first Monday in December. Dr. Henry Head, of St. Mary's Hospital, London, in a recent communication defines physical exhaustion as the loss of capacity to dominate impulses derived from environmental stimuli.

Due regard for some of these disintegrating phases of our everyday life would free the energies for constructive effort. They are neglected at the peril of raw nerves, petulant dispositions, and general ineffectiveness.

A Note on the Epidemiology of Golf —A Chronic Incurable Disease

GOLF—O. D. Kolf, a club—is a chronic, incurable disease occurring in all climates, at all ages but most often among males in the fourth decade, and characterized by alternate periods of mental elevation and depression. The disease is ushered in by an acute myalgia of the muscles of the trunk extremities and delusions of wealth as evidenced by the miscellaneous purchase of bags, clubs, and balls. In the initial stages there is a marked change in the vocabulary and apparently meaningless words such as tee, lie, whiff, and dub are used. In the chronic stage there is a settled and prevailing profanity. Physically the disease is characterized by the loss of the equatorial mid-riff, general hardening of the musculature, tanning of the face and forearms, and general increase in the coordination of brain, eye, and muscle. A marked irritability alternated by periods of beatitude is to be noted in cases of long standing. The disease is most violent on Sundays and holidays. Although associated with insect life, golf is spread by intimate contact with persons in the chronic stage. A sub-variant, known as chin golf, is recognized.

Golf appears to have had its birthplace in

Holland and numerous paintings depicting its victims putting at a stake set in the ice are still extant. It is believed that these represent merely the hibernating form of the malady. The stake is still used in different form.

Introduced in Scotland by sailing vessels, it spread rapidly in spite of many legislative acts and formed there an endemic focus, which has never been eradicated. Thence it spread into England, forming several virulent sub-foci, one of the most active still remaining at Blackheath, also famous for its highwaymen. The connection between the two has never been established.

Modern transportation has facilitated the distribution of golf round the world, at first gaining entrance to the larger centers whence it has travelled out to the more sparsely settled districts. Thus from an urban disease it has gradually become metamorphosed into an affliction of town and country alike. This spread cannot but be viewed by other than alarm by health workers. A disease which may attack both sexes and all ages, which reduces the morbidity and mortality rates, which promotes longevity and delays senility, strikes at the taproots of the health-workers' livelihood.

Worst of all, all repressive measures seem futile. The clergy has preached against it as an enemy of church attendance; business men have realized that they must either give up golf or business and have sacrificed the latter; poets have raved over the fact that nothing will rhyme with it; yet it has crept forward, insidiously attacking all with whom it come into contact. One armed men have succumbed to it; advertisements for artificial limbs now show a central figure just about to smite or dub his drive; and as for the collar and shaving soap ads, what would they be without golf? Women no longer exercise with a crochet needle and a box of chocolates; instead they wield a mashie and abuse the careless caddy. Yes, golf has come to stay and relief can be gained only by submitting to the inevitable infection.

Washington Conference Clears Pellagra Situation

THE conference of southern state health officers, held early in August at the call of the Surgeon General of the United States Public Health Service to discuss the pellagra situation in the South, reassured the Nation that there was no occasion for undue concern. A letter from the President to the Surgeon General, calling attention to famine and pellagra sweeping the southern states, was prominently reported in newspapers throughout the country, to the great dismay of representative southerners, who denied the accu-

racy of the report. The southern health officers attending the Conference also felt that an irreparable damage had been done the South and desired a public retraction of the statement.

The classic researches of Goldberger have demonstrated that pellagra is not communicable but a disease resulting from deficient diet—lack of lean meats, milk, eggs, and legumes. Obviously, the family diet is directly influenced by economic conditions so that periods of financial depression are generally accompanied by an increase in pellagra incidence. Sydenstricker, in *Public Health Reports*, under date of October 22, 1915, and the experimental work of Wait, reported in Bulletin No. 221, have accounted for the higher incidence of pellagra in rural than in urban sections of the country on the basis of the greater shortage in the country of the essential proteins than obtains among the poor of the cities.

Pellagra was first recognized as endemic in this country in 1908-1909, and attained its maximum incidence in 1915 following the depression brought on by the outbreak of the European War. During the five year period 1914-1918 there was an average annual mortality of eight thousand deaths from pellagra, and probably one hundred sixty thousand cases. In 1919 and 1920 there was a sharp decline brought on by the prosperity of the years 1918-1920. Indications afforded by the trend of pellagra incidence in certain representative localities clearly point to an increase of about 25 per cent in the pellagra incidence in 1921 as compared with last year, or an estimate of five thousand deaths and one hundred thousand cases for 1921. Despite this increase, the figures are distinctly lower than those during the period 1914-1918.

The following extracts from the resolutions adopted by the Conference indicate the conclusions arrived at by the health officers:

After making an investigation using all information available, we do not believe the situation warrants or should occasion any undue alarm. The indications are that there will be an increase in pellagra this year in localities in certain states where the disease has been endemic, but data in hand show in an unmistakable way that the number of cases and deaths from pellagra during 1921 will still be less than the annual average during the period 1914-1918.

There is no condition approaching a famine or plague in the South. It is obvious that this is a clear case of misinterpretation of terms, an incorrect analysis, and as a result statements have been made that are erroneous and misleading to the public.

There is much obscurity in the recrudescence of disease and a situation of this kind calls for careful consideration, but there are confronting the Nation health problems of much more serious moment than pellagra and it is hoped that popular interest will be similarly forthcoming in the efforts to eradicate these diseases, and to promote the national vitality in general.

TWO decisions of far reaching importance as affecting the future relationships of the British medical profession were reached in the early business sessions of the British Medical Association recently convened at Newcastle-on-Tyne, the one growing out of the recent violation of professional secrecy in a civil court, and the other out of the opening made last year for the affiliation of the Association with non-medical bodies.

It was practically a unanimous opinion that the Association should use all its power to support a member who resists giving evidence on duress, and that it can hardly be to the detriment of justice if "for the present the value of the Wassermann test and the differential features of the Spirochete group are ruled out of court." Another year must pass before this decision becomes the considered policy of the Association. Meanwhile, means are to be sought to reconcile medical and legal views to the benefit of the community.

Affiliation with non-medical health agencies was held by the Association to be undesirable. It was the decision of the meeting that the value of identity and individuality is so great an asset as not to be weakened in speaking to the Ministry of Health with the united voice of all health interests. This is not to be taken, however, as a decision to rule out conferences before presentation in order to thresh out mutual difficulties.

VARIATIONS among state and Federal laws often embarrass manufacturers and distributors of foods, drugs and medicines, but the many difficulties in the way of any effort to frame Federal food and drug legislation so that it will invariably and effectively meet the local needs of each and every part of the United States are emphasized in connections with Bill S. 1887 recently introduced into the United States Senate.

The Bill provides that no law of any state, city, or municipality, relating to the adulteration and labeling of foods, drugs, or medicines shall apply to or interfere with the sale of any such article after it has been transported to interstate commerce.

Interesting complications suggest themselves as arising from making such "package" goods subject only to Federal jurisdiction. Milk, poisons, narcotics, habit forming drugs, fraudulent advertising, goods spoiled in the original container, would all be in a hopeless tangle unless such a bill effectively occupied the local field with courts, inspection forces, and other means of administration.

Medicine As Related to Workers and Production

*Exploitation Gives Way Before a New
Sense of Opportunity and Responsibility.*

BY CHARLES A. ANDREWS, PRESIDENT OF THE ASSOCIATED INDUSTRIES OF MASSACHUSETTS, BOSTON, MASS.

THE subject of this symposium is very comprehensive, so much so that the time allowance of twenty minutes for the presentation of each of its several phases necessarily limits the discussion to the more outstanding problems. But the mere fact of holding an open forum of this kind shows that progress has been made in the field of industrial medicine. Ten years ago it would have been impossible. The topic itself is a comparatively new development. Ten or fifteen years ago nobody cared very much about the health of the workers; and it is almost true to say that no industries or industrial managers had concluded that they had any responsibility in the matter or that there was any service that they could perform with relation to the health and physical condition of their employees. But during the last few years various experiments have been undertaken and some achievements made. As this new sense of responsibility for health has been growing, it has gone through the same transformation that most new ideas have to go through in the process of getting established. A lot of false starts have been made and mistakes have crept in. What at first looked like a promising lead to accomplish something has, on further experience, turned out to be a false ideal. But, with all the mistakes that must be admitted, progress has been made until today the employer of any considerable number of workers finds—

We are presenting in this series of papers a symposium of addresses made before a joint meeting of the Associated Industries of Massachusetts, the Boston Employment Managers Association, and the American Association of Industrial Physicians and Surgeons held at the Copley Plaza Hotel, Boston, Mass., Tuesday, June 6, 1921.

The meeting was so arranged that representative men gave expression to the typical viewpoints which are shaping the course of industrial medicine today. Whatever the contribution made by industrial medicine, it will be arrived at through a working compromise effectually representing all interests.

not as a matter of paternalism—not as a matter of charity in order that he may give something with no hope or expectation of return—but as a matter of sound business methods and as a matter of discharging an obligation toward those who are associated with him that there is something to be done in part by the management or under the guidance of the management, with relation to the health and physical condition of his employees. The conception is beginning to get established and is founded on three or four reasons:

One is for the dollars and cents, as affecting the employer; another, for the dollars and cents, as affecting the employee; and another, for the spirit of contentment and optimism and good Americanism, as affecting them all. During the last few years development has been on the basis of this ideal. We have already overcome some of our early mistakes and begin to see ways of eliminating more of them. The subject is comparatively new, but its application to the economic life of the community is increasingly broader.

On the Basis of Reason

There was opposition when the American Association of Industrial Physicians and Surgeons decided to hold its annual meeting and join with representatives of industry for the consideration of some of the problems which these new ideals in industry presented. The removal of this opposition illustrates a fact which is becoming more and more evident as the days go by—that the old conceptions of hiring laborers, working them as hard as possible, getting the maximum production from them, selling the goods, and having no concern for any of the human relationships or any of the vital interests of the employees or of the management, were all wrong. Those days have gone by, and a finer sense of opportunity and responsibility has come into industry to which industry is responding. The response is not complete yet, but a

fine start is being made toward a greater vigor and a better conception of its opportunities, its duties, and its responsibilities.

In the various societies in the communities where we are established, in which we and our employees work and live together, not only during the factory hours, but also during the entire week, it means much to evolve this sense of mutual opportunity and responsibility. As industry has visualized that picture of mutual interest and mutual service, the medical profession has aroused itself from its old self-satisfied orthodoxy, and has produced a virile group, traveling new paths, honoring themselves and their profession, and making their profes-

sion of greater value for the whole community than it has been before. So that, as we consider some of the problems and recite some of the past experiences we are justified in regarding the changes so far accomplished as being on the whole constructive, remembering meanwhile that the ideals of industrial medicine are not yet achieved and that, however great the progress made in the last few years, the distance yet to be traveled is vastly greater than that which has as yet been covered.

Evidence of Progress

A conference such as this could not have been called ten years ago. Not a single industrialist would have

taken part in it. Few, if any, physicians could have been induced to come. There would have been almost no stories to tell, no experiences to recite, and very few ideas to express. If, perchance, some one had drifted into an assembly of this character and expressed an idea with relation to the matter of medicine in industry, he would have recited to a cynical audience. We have passed well beyond those days; so that this body, representing industry, industrial management, and industrial medicine, is a group of idealists who have accomplished practical things, and who, to an appreciable extent, have already shown that they can make dreams come true.

Production Manager's Interest in Industrial Health

The Efficiency of the Men is a Fair Index of the Value of Health Engineering.

BY JOHN SPENCE, WORKS MANAGER, NORTON GRINDING COMPANY, WORCESTER, MASS.

WE ARE probably approaching a period of years of such keen competition in business that many undertakings adopted without careful consideration in the boom times of the past six years will now be submitted to careful scrutiny. The time for doing a thing because others were doing it or because it seemed to offer a remedy, though an expensive one, for some industrial problem has evidently gone by. Many who, because of several successive years of good business, had arrived at a state of mind where a return to normal or sub-normal times seemed to them an impossibility are now wishing they had allowed time to solve their questions and that the money spent on quick but unfortunately short-lived solutions was now in the treasury available for much more important issues.

Discrimination Necessary

In the general retrenchment that is now going on and must continue to an even greater extent, every cause of business expense will be carefully considered. In some cases the reaction will be as extreme towards the lopping off of expense as it recently was towards the acquiring of it. Among other more or less recent industrial institutions to come in for its share of scrutiny as to the real value to the corporation will be the shop doctor and the shop hospital.

I do not know why so unimportant a layman as myself was invited to discuss the subject of the shop doctor. Possibly it was because someone heard me express what were called, before the slump, old fashioned ideas on collective bargaining or industrial democracy among the vagaries of a recently deceased period and naturally concluded that I might furnish some fireworks in a conference of this kind, but if so, I must disappoint him because he happened to pick on a man who is very much in favor of the shop doctor.

A Change of Heart

I have not always been in this frame of mind towards medicine in industry and I have no doubt that many members of the American Association of Industrial Physicians and Surgeons have had to convert some of their shop men just as our Dr. W. Irving Clark has converted me.

My experience was gained in shops where a daub of hot glue was a cure-all for cuts and lacerations. There were those among the old fellows who stated that a cobweb laid across a cut was the quickest and surest cure. I never had a chance to try it because even in my benighted period shops had arrived at a state of sanitation in which cobwebs were no longer allowed to accumulate. We looked down on the cobweb advocates as being remnants of an ignorant past

and stuck to our glue. Possibly, being of those who dealt in material things, we found it easier to stick to glue than to cobwebs.

Another thing impressed upon us was that one did not quit work on account of what we were prone to regard as somewhat trivial accidents of a kind that today would lead the doctor to send a man home or to extend expert special attention.

When, therefore, a shop doctor began to be advocated I was among the doubters. My company is fortunate in having in their medical director a man who not only can but is willing to argue and demonstrate a point without arousing rancor or personal feelings. At first I was doubtful of the value of complete physical examination. Today, because time has proved its very small per capita cost and the quite large possibilities of its usefulness, I favor it.

At first I thought we were on the road to make mollicoddles of the men when it was desired to treat at the hospital every abrasion, no matter how slight. I thought the foreman and time clerks could continue to take care of minor cases and could send on to the doctor those worthy of his attention; but the fact that there is no definite borderline between cases that can be handled this way and those that should have expert attention, and the sight of one or two bad cases of blood poison, showed

me the relative unimportance of an apparent slight saving of costs. So far as making mollycoddles of the men is concerned, that illusion was eliminated by the boys who went over to France. I have from the first been in favor of what I would call the regular work of the doctor, that is, the caring for cases of illness. Here is where the shop doctor not only does a humanitarian act, but can go far toward healing any ill feelings in industry.

The Placing of Blame

The man who is bruised or cut may with some justice look on others as being responsible, but he can hardly blame anyone but himself for most of his physical ills. Because of the opportunity for engendering goodwill through such cases, too much care cannot be exercised in selecting a shop doctor. He must be fully aware that while his job is primarily to relieve distress and to reestablish the worker to full earning power, an equally important part is the team work he owes to the production officials in attempting to build up the proper shop spirit.

A successful shop doctor, in addition to being a good medical man in whom the men have confidence, must have ability as a leader and organizer. With this ability he will be enabled to enlist the cooperation of foremen in the furthering of plans that would fall flat without the foreman's sympathy. Illustrations of such cases are: the bettering of working conditions, the re-examination of men who are failing physically, and the investigation of absenteeism.

While I do not believe that paternalism in general is good, yet a little paternal-like advice is usually acceptable. In this line the shop doctor can help the production men by doing his best to maintain the health of at least the more important men by occasional re-examination and advice with regard to right ways of living. In spite of the recent constitutional amendment, most people do not as yet drink enough water. The shop doctor, who can advise or scare a corps of important men into acquiring the water habit will have paid his way.

The departments having to do with sanitation, safety, and health are so closely related that whenever the right medical director can be found all of these should come under his authority, in addition to which functions he should be a man to work towards the bettering of living conditions and welfare work in general. This is especially important because of the fact that the ignorance that

leads to the necessity of such work, usually involves the need of medical training.

From the standpoint of a production man the shop doctor is necessary not only because of the good he can do in building up shop morale, but because our own figures prove that our hospital service pays its own way in productive hours saved plus the cost of turnover that would result from misplaced physical defectives.

For the past twenty-seven years I have been in contact with men in the shop. I have seen men comparatively young in years gradually go down physically and mentally because they had no one to give them a bit of advice as to the care of teeth, proper food, and proper sleeping conditions.

The effect on production and the profits of the corporation employing such men can, of course, be only surmised, but it must be quite a significant item, especially in cases of men who are paid for extreme skill or knowledge rather than for physical effort. From a cold business standpoint the unskilled can be replaced by young and vigorous laborers, but it is not possible without great loss to replace an accumulated knowledge of special lines of the business, acquired by years of experience. This loss is going on in shops everywhere every day and I am certain from a few experiments we have carried out that a great proportion of these cases of men "running down hill" can be cured if a shop is efficient in having the right kind of a doctor.

A shop doctor, because of the fact that his patients are members of his own industrial family, must acquire the more or less paternal attitude. His job ceases to become simply a means of earning a living and takes on more or less the attitude of co-operation with the management of

the business for increased production on the one hand and on the other a sympathetic interest in the worker for the sake of building up happier, healthier people.

The physician in private practice, because of the fact that his services must be paid for by the piece—to use a shop term—cannot follow up his cases as he would wish to if it were within his power to do the best thing for each patient. In the shop, however, there is no such restriction and the shop doctor may, therefore, gradually take the same interest in building an improved production of his department as an index of effective service that the engineer now takes towards the output of the plant.

This attitude may be regarded as somewhat visionary and the outlook of the up-lifter. I am quite convinced, however, that even from the standpoint of a money valuation there is just as much if not more profit in this kind of work as in the careful maintenance of the plant itself.

There are few men today who would consent to the dropping of shop cleaning or sanitation work, yet our figures show that the entire cost of our hospital work amounts to only three-tenths per capita of what we pay for shop cleaning. Both are necessary and both in the long run pay dividends.

Airplane Medical Service

The French government has built six airplanes for use in the colonies where the distances the doctors have to travel are enormous and where there are no medical facilities. The planes carry complete medical and surgical kits, and are so constructed that patients seriously ill or injured may be carried from remote regions to hospitals.

The above graph originated in the Woman's Bureau, New York State Industrial Commission. It is designed to show the lines of investigation involved in fatigue studies and their several relations to the problem as a whole.

The Consultant in Industrial Medical Service

Industrial Health is Public Health and Both
Are the Proper Objects of Collective Effort.

By WADE WRIGHT, M.D., INDUSTRIAL CLINIC, MASSACHUSETTS GENERAL HOSPITAL, BOSTON, MASS.; SECRETARY OF THE DIVISION OF INDUSTRIAL HYGIENE, HARVARD MEDICAL SCHOOL

IT IS but fair to state at the outset that this contribution does not come from an industrial physician, one directing the health activities of an industrial organization, but from a doctor quite on the outside, looking upon the activities of many industrial medical establishments and as one whose daily duty it is to consider the ailments and disabilities of industrial workers as they are found in a large general hospital.

Most people need a job and for one reason or another, most want a job. Having found it, if it be truly a job, the worker's life revolves about it. The nature of the work, the hours of labor, the compensation received; these determine in large measure the manner of life of the worker, his lodging, his food, his clothing, his opportunities for recreation and for intellectual development; and as for him, so for his family and those dependent upon him.

If work be so dominant an influence in regard to his economic and spiritual welfare, it is surely true that it is as definitely related to his physical well being. I do not mean to imply that a worker, for example, of subnormal mind and body, ignorant and improvident, is such because of the work he does, but rather that upon this worker, whatever his physical and mental endowment may be, industrial life exerts influences for good or ill.

The people of our country are in large part an industrial people. They live by industry and industry by them. Whatever we may some day come to consider the rights of the community and of the state to control all essential industries as public utilities, it is true today that with varying standards of honesty and justice our industries serve as public utilities, either public luxuries or public necessities.

It is in this close interrelation, this identity of the community's good and the good of industry that I believe industrial medicine is rooted. The health of labor in a shoe factory is the health of the people of a shoe factory town. The public health of an industrial community is with reasonable exactness the health of the industrial workers of that community.

Industrial health is so nearly identical with public health that it would seem as if industrial hygiene were properly a unit of the community health service.

The fact remains, however, that in few communities has medical organization developed efficient means of recognizing and promptly treating incipient disease. If such service is desired in industry, industry must provide it.

The character of a community is governed largely by industrial conditions and through such means as the physical examination of labor and the periodic re-examination of employees are afforded unlimited opportunities for constructive health work.

A sick town means sick workers and sick workers mean a sick factory. The factory cannot be cured, except by curing the sick workers.

Few people are wholly well, many are far from well, probably most are definitely handicapped by physical and mental disabilities. We still lack satisfactory statistics regarding morbidity and particularly industrial morbidity and sick absenteeism, but there is reason to believe that the conventional figure of nine days' sickness per worker per year is low rather than high. The cost of this is not totalled when to the lost wages of workers is added the immediate cost to industry. Sickness, and its care, unemployment and its attendant hardships, destitution and pauperism must all be reckoned in.

We all pay for this, but industry, absolutely dependent for best production upon the best health of producers pays far more than need be, if it fails to support every reasonable effort, in industrial establishments and without which tends to promote the health of its directing and operating forces. For the individual plant offering such support there is additional advantage to be gained over competing organizations which consider the promotion of

health wholly a concern of the individual and of the community medical and public health personnel.

No Right to Be Sick

We deny the right of an individual to take his own life, but it would be considered generally an infringement of that popular phase of freedom called "personal liberty" to deny an individual the privilege of being sick when and as he pleases, to deny his right to impose his own physical worthlessness upon his fellows.

Medical organization has in few if any communities been perfected to such a state that it makes readily available the service necessary for the prompt recognition of incipient disease and for the treatment of various disabilities and the remedying of defects. If industry finds such a service desirable, it must provide it.

It should seldom be necessary to maintain the facilities for such service wholly within industrial medical organizations. A plant medical service is usually strengthened by close working relations with community resources. The relations of the company physician and the local practitioners may be adjusted in conformity with the Golden Rule, which, happily, has not as yet been found unconstitutional.

In certain mechanical industries the incidence of accidents is such as to demand much surgery, but it is obvious that the health of a working force cannot be safeguarded and maintained by surgical dressings alone. It is through such means as the physical examination of labor applicants, through periodic re-examinations of employees, through the development of good will and confidence of workers in the medical department and the consequent appeal for the advice of the plant physician that the opportunities for constructive work are to be found.

It is thus that defects, perhaps of long standing, may be found and remedies suggested and made possible; that potential sources of disability may be discovered and prophylactic measures instituted, that early disease may be detected and treatment offered.

Service of this character can only be rendered by able personnel and it is economic folly for the administration of an industrial organization to believe that practically any doctor or any nurse can be depended upon to do work of a satisfactorily high standard. The interests of successful industrial physicians and nurses cannot be their own interests or the company's interests, but rather a just mingling of the company's interests with those of the patients who come to them for professional service. It scarcely need be stated that competent physicians cannot be secured unless their compensation be roughly commensurate with their worth.

Costs More, Worth It

Good industrial medical service is not to be had cheaply, yet it seems that it is worth what it costs and more, for ill health is so costly. It seems worth while. Establishments installing medical service do not abandon it. They may reduce it in times of depression, but the tendency is almost invariably toward development, toward an increase in the range of health department activities.

Industrial physicians rise from time to time to proclaim vehemently that industrial medical service pays and

they are followed by plant executives who admit and may even enthusiastically endorse this fact. It probably does pay, in dollars, but health and ill health are elusive things with which to reckon. One may perhaps estimate the cost of known ill health with fair accuracy, but it is not so simple to state with precision the influence exerted by a plant medical department upon such matters as absenteeism and labor turnover, neatly dissociating the part played by the medical department from the effects of other personnel activities.

If an industrial medical service is so good a service that the physical standards for employees are advanced, if workers keep well or when sick get well more promptly than they did before the medical department was established, and if there is no waste in the administration of the department, it probably pays in dollars.

Industrial physicians, about the time they make announcement of their departmental dividends, are liable to state with ponderous seriousness that the "object of industry is to make goods and sell 'em at a profit." If one is present, a personnel man may rise to give utterance to the same sentiment. If the speaking continues the thought will probably be

again expressed, with the possible addition that without this goal of industry, the making of goods and the selling of them at a profit, all else fails, even jobs for industrial physicians and personnel directors. It would seem to be true, for many earnest men state it earnestly.

In this company I would be so ungracious as to say that the interests and ideals of many industrial executives are such as to shake my belief in the soundness of this statement of the first object of industry, the creed so solemnly pronounced. A similar creed for all men might be—"I believe the object of life is to eat from time to time—without this, all else fails!" "To make goods and sell 'em at a profit" cannot be the object of industry, if industry is truly an expression of a people, an expression of idealism in action. It may be that with the wholesome sentiment which is rather likely to abound beneath the case hardened exterior of the hard headed business man, it may sometime be admitted more often than now that industry is no little concerned with the making of goods at a profit, but also with the making of men.

The progressive industrial physician wishes to have a hand in both of these tasks.

The Medical Department Proves Its Value

Cooperation On the Part of the Men Is the First Requisite of Success.

By J. A. ROBERTSON, MANAGER OF THE CAMERA WORKS, EASTMAN KODAK COMPANY, ROCHESTER, N. Y.

THE subject under consideration is "Health in Industry." This is a big problem, and as an illustration of how medical service may develop, I will relate to you briefly how the Eastman Kodak Company started on this line of work. In 1908 I took charge of the Camera Works. I had worked for Mr. Eastman twenty years before that, but had left him and gone into business for myself. Later, I sold out to the Eastman Company and went back to work for him. While in business for myself, I learned some things which I have not forgotten, because, when you have to worry as to where the next Saturday night's payroll is coming from and how you are going to sell enough goods to meet the payrolls and the other obligations, you learn something that you do not learn in college or from books. I never went to college,

having gone to work at fourteen years of age, and became a foreman, superintendent, and, later, a manager. So I think I know a little of the psychology of the worker, and I believe yet, despite scientific management and a lot of other things, that in order to get results, you have to get the good will of the employee and enlist his sympathy and his respect for fair dealing. You must get him to want to put it across; then he will do it. The methods that may be used to get him into that attitude differ. It is not essential which is used, so that you get it across; but the medical department in our large industries has become important in this respect, and how much further it will go, no one can tell.

Shortly after I went to work for the Eastman Kodak Company, they were carrying liability insurance, and left

it to the tender mercy of the insurance adjuster to take care of the injured. Soon after I went there, an old employee met with a serious accident, which resulted in the amputation of one of his hands. I did not feel that it was right to leave his case with the insurance adjuster, and took it up with Mr. Eastman, who said: "Pay the man his wages while he is off. He is an old employee." I said, "How about the next case? You will establish a precedent. I think we are big enough to cut out insurance, carry our own risks, and take care of the employees. While in business for myself, I did not carry liability insurance, but when a worker was hurt, I got the best doctor I could to take care of him, paying the man half his wages. I had no suits for damages and the attitude it is possible to create with men by humane

ALLOWANCES FOR ABSENCE CAUSED BY ILLNESS

Period of service	Proportion of wages payable	Maximum period covered by these payments during second 6 mos. of service or any year thereafter	Maximum weekly payment
Less than six months.....	1/3	6 weeks	\$10.00
6 months, but less than 1 year.....	1/2	13 weeks	15.00
1 year, but less than 3 years.....	2/3	26 weeks	20.00
3 years, but less than 5 years.....	3/4	26 weeks	22.50
5 years or over.....	3/4	26 weeks	22.50

No allowance in any case for first week's absence.

and just measures, treating them as you feel they should be treated, brings the biggest dividends."

After that conversation, it was decided to appoint a Safety Committee consisting of the managers of our six Rochester plants, and I had the honor of being made chairman. We instituted an intensive accident prevention campaign. The first thing was thoroughly to safeguard the workingman. To convince the employees of the seriousness of your intentions you must do your part before asking them to do theirs. We used lantern slides, motion pictures, and illustrated bulletins to get the education over to the workers, and the decreased number of accidents proved the value of the instruction.

Health Pays Dividends

Carrying our own insurance was a demonstration that it was not only philanthropic but economic, and it pays big dividends to the Eastman Kodak Company.

We employed for a while a part-time doctor to take care of the accident cases, but the requirements grew until we found that we had to have our own physician. The department gradually increased and a year or two afterwards we put in physical examination, additional doctors, nurses, and attendants.

The problem is not yet solved because each day new questions are coming up. We find tuberculous cases. Our doctor told me recently that there were two hundred fifty cases of incipient tuberculosis and no institution could be found to which they would be admitted. It is an awful thing to leave a man sitting on a mine of that sort, when he could be cured by proper attention. We have operated on over one hundred cases of hernia with only two failures, which is a pretty good record. Some doctors do not average as well.

May 1, 1920, we put into effect health benefits, paying the employees in proportion to their length of service, a certain portion of their wages while they are off sick, as shown in the above table.

It is always important to remember that you cannot by any system of bookkeeping figure the results in dollars and cents as a paying proposition, but when you turn to the increase of wages since 1914 and figure the increased production that we have in our factory, it is not difficult to prove that it does pay. Since 1914 earnings have increased more than 120 per cent, and so far as it is possible to determine by comparison our labor cost has only increased 27 per cent during the same period. What part of this increase in earnings the medical department is responsible for, no one can tell, but we are convinced that a good ratio of that increased

production is probably due to the care of the physical condition of the workmen. It is not a question alone of producing goods by working the men hard and making money. The employer to be successful must look out for the health and working conditions of the people under him and educate them in welfare and thrift; and unless he is big enough to put these things over and get the cooperation of the employees, he will be a failure in the manufacturing business.

While we are passing through this great business crisis, there may be a little falling off in interest among those who have not proved the benefit and the merit of health in industry, but with those who have and are interested in the development of real, red blooded citizens, the matter is different. The boys who came back from over there are helping us because the war opened up new avenues to them and they saw the possibilities. They believe as do we all, that every man should have equality of opportunity to grow up and labor for himself and be paid what he earns, and not on a scale set by someone else.

The Physician's Viewpoint

By OTTO P. GEIER, M.D., CINCINNATI MILLING MACHINE COMPANY, CINCINNATI, OHIO

THE introductory remarks of Charles A. Andrews, chairman of the Joint Meeting, giving a splendid outline of the whole philosophy of industrial relations, followed by the tribute of Mr. John Spence to the value of medical service in industry; Dr. Wright's thorough exposition of the social and economic side of industrial medicine; and Mr. Robertson's generous and humorous testimony, leave little for me to say in regard to the industrial physician's viewpoint. I wish, however, in my official capacity to express the deepest appreciation of the value of this representative conference as a testimony to the importance of the program initiated by the American Association of Industrial Physicians and Surgeons. In the six years that this organization has been in existence there have been times when the physicians have lost faith in industry, when their courage and enthusiasm weakened. Personally, however, I have always had the faith that somewhere, somehow, sometime, industry might get the proper appreciation of its responsibility towards the worker and, particularly, might exhibit a consistent interest in

the worker's health, and that this interest in the worker's health might be on a perfectly selfish basis, as a mere matter of production, not only as a gain in output per man, but would secure something far more valuable than that, an improved state of mind in the employee and the employer, a better relationship between labor and capital.

Not an Artificial Contact

This can come in no finer way than through the series of contacts and elbow-brushings that come about in the industrial clinic, where the doctor acts as a real friend to the worker. The true industrial clinic is not an artificial contact point but is an institution with a personality that has within it the power to know what service is needed and to render such service, that expresses its desire to help in natural channels. It is here where the physician can put his scientific attainments at the disposal of the worker, who in the main has always been denied the opportunity of having intelligent medical service for himself.

This type of social service and every day helpfulness, built upon the

century old relationship of the physician to the patient—that of priest, confessor, and advisor—is valuable when set up in industry, particularly if it is not set up on a dividend paying basis but undertaken because it is just and right. When industry sets up this type of service to its men as an integral portion of its organization, then we may actually believe that the first round in the better relationship between labor and capital has been climbed.

The size of this job and the need of this service are probably best indicated when we recall that 35 to 40 per cent of the young men of our country by physical examination proved themselves unfit to tote a gun in the service of their country. This is an industrial country. Most of us, in the cities at least, are working directly or indirectly for industry. When we stop to realize that our present mode of living and doing and earning has finally produced a type of manhood 35 per cent of whom are deficient for war purposes we naturally ask ourselves whether this condition does not also measure the mental and physical deficiency of society as a whole in peace time. Then we naturally ask ourselves a second question, whether this physical and mental unfitness does not explain a great deal of the present unrest, the state of mind of many men toward society, toward labor, toward capital, toward organized industry.

From long contact with the industrial clinic I developed the hope that in the industrial clinic we might have produced a better state of mind, both in the employee and in the employer, that will make for a better program of social relationship, a better type of citizenship.

We talk a lot about Americanization; tons of literature are distributed on the subject. Our minds revert chiefly, however, to the foreigner and not to our English speaking people. Nevertheless, the real job of Americanization goes far deeper than that and includes the intelligent coping with such movements as are fostered by the I. W. W. and the communist.

What industry needs above all things is to have the honorable employer properly interpreted to the employee, and the honest employee properly interpreted to the employer, if we wish in the future to prevent the fierce conflicts between labor and capital. There must be a laying of the cards on the table between the man at the workbench and the man in the office, in order that the fellow

in the office may understand the mind of the worker in the shop, and *vice versa* that the worker may understand the man in the office. They both must get the idea that the other fellow is a pretty decent chap after all when you get to know him.

I believe that industrial medicine in a labor policy is something industry must reckon with. I think it can be made a most natural approach to the subject. There is nothing artificial about industrial medical service. It is needed, and it is used. It is never looked upon by the worker as just another mechanism for the employer's advantage, for good service of this type sells itself. It is usually set up by the employer who wishes to render a real service to his men, and in this it is unlike so many schemes of employee-relationship which were hastily organized to meet an emergency labor problem. But only a doctor of the right sort, it goes without saying, may render such service. Industry, however, must learn that out of a cheap doctor can come only a cheap result.

Conditions Problematical

It has been difficult for me to meet our Association this year with anything like the enthusiasm and energy with which I have approached every other meeting. Up to this time, we have always been on the ascent. Industrial medicine was growing, pushing forward, and progressively building up in the minds of the profession the idea that here was something that had come to stay; that industrial medicine was going to make a real contribution to society, and that capital was backing it up and going to help push it forward. We felt justified in going out and acclaiming that fact to the profession at large and urging them to leave individualistic treatment and take up the supervision of great masses of society, thus employing their energies in wider fields. But, the world cataclysm has also affected the industrial physician. At least, a number of them have lost their positions. This is a very serious thing. We cannot hope to hold doctors in industry when, with the turn of the wheel, or the lack of the turn of the wheel, their jobs may cease. They do not have to come to industry for a living, and they should not come to industry when that living is uncertain. Unless we can operate and work continuously in industry, we cannot stay in industry. Some of us are on the firing line, trying to induce others to come into the work; but we have got to stop doing this un-

less industry finds a way in which the well trained, socially minded physicians can give themselves to this work, assured of a continuance of work; otherwise, the progress of industrial medicine is really seriously threatened.

My present plea, therefore, is for industry not to take this matter of industrial medical development too lightly. The opportunity for the medical profession to serve society and industry is just emerging. We have just scratched the surface in this matter; because, linked up with industrial health work are the other phases of community health work, our state program, our national program, which today are limping along under partisan control. Today medical men are out in the front, begging the communities to save themselves from ill health, which means lowered production, lowered per capita wealth. When industry finally seizes this idea that it pays the community—of which the industry is a part—to be well, then industry will take up the fight for health, better living conditions, and better working conditions. Then we shall have in the Nation, the state, and our cities, health departments free from politics and supplied with sufficient funds. After all, industry produces much of the wealth of the country. She finally pays the bill for ill health. She can better afford to pay for its prevention.

Labor Union Establishes Health Department

Believing that "in sanitation and health as well as in economics the salvation of the workers depends upon the workers themselves," the International Ladies' Garment Workers Union of New York City has opened the Union Health Center. Located at 131 East 17th street, in a building which was bought, reconstructed, and equipped by eight locals of the union at a cost of \$100,000, the health center is described as "a center for all sanitary, medical, and health activities of the International Ladies' Garment Workers Union Locals in New York City to serve the health needs of 100,000 garment workers." Provision is made for medical examination of all applicants to the Union, for examination and treatment of members entitled to sick benefits, for first aid and surgical treatment of the injured. There is a fully equipped dental clinic where members may secure treatment at very moderate cost, a workers' diagnostic clinic, and a workers' life extension institute.

Medical Service As Affecting Industrial Relations

Specific Problems, But Not the Whole Load of Medical Treatment, Are on Industry.

By HOWELL CHENEY, CHENEY BROTHERS, SOUTH MANCHESTER, CONN.

THE ground has been so well covered that there is really nothing left to do but to take up the challenge thrown down by Dr. Geier, who turned to us and asked, "Where are we at?" I may as well confess at the start, that I am not at all sure that I know just "where we are at," but I have a fairly clear idea as to where we are going. There are three parties to determine the direction. We find the physicians, in their "whereatness," in a frame of mind perhaps of doubt, perhaps of disappointment. They have seen men whom they knew to be first class men dropped from the ranks of the industrial physicians. They have seen idealism thrown out of doors, and they ask "was it for this that we gave up our chances in a profession where promotion was contingent upon individual effort? Was it for this that we sacrificed that ancient bond between a physician and his patients and threw ourselves under the control of a corporation?"

Measure of Progress

I appreciate some of the reasons and some of the causes of these doubts and disappointments. We have seen, in this endeavor, many fools rush in where angels might have feared to tread. We have seen, during the war, employers undertaking work of this kind without having gone down to the roots of what they were doing—without having perhaps any more definite purposes than, on the one hand, the promotion of an advertising campaign which they thought might bring labor to their doors; or, on the other hand, the half-baked thought that the providing of medical attention was cheaper than increased wages. Or, perhaps the sentimentalist had gotten hold of them and really made them believe that they were their brother's keepers in this field and that it was up to them to see after the health of their employees in a paternalistic fashion.

These failures give no cause for discouragement, as they merely represent mistaken or insincere attempts to carry out a half-thought-out program, or no program at all. If I mistake not, the physician's doubts as to the direction are due to

Industrial medicine is general medicine plus several specialties. Each industry presents in addition to sanitary problems specific physical and physiological elements. With the personal equation are bound up questions of relations. The successful industrial physician, therefore, needs to be scientific, ethical, sincere, open-minded, equable, and always keen for further research into industrial health conditions. His special work should entail no material sacrifice or moral concession.

the failures of misguided efforts, rather than of fundamentally mistaken purposes.

Where is the worker at? How far along has he come? I doubt whether we can measure, or whether any of us have the means of estimating, the force of the program for public health that the war put over. To millions of workers the idea has come that if health is not a purchasable article, it is in some indefinite way an obtainable article. On the part of the worker a trust in its possibilities, a knowledge of its opportunities, has taken the place of suspicion and doubt. There your field is fertilized and your path is open for development.

Where is the employer at? Just now he is spending a good many hours a day trying to figure the balance on his ledger and it is often a discouraging problem. You have no idea how black—how hard the pull is. He is at the point of view where he is questioning, for the time being, not "Does this thing pay in actual dividends?"—because there are very few who are fools enough to believe that its value can be measured in dollars and cents—but, is it really worth while? He goes to every physician and makes him give grounds for the faith that is in him. These articles of faith must be expressed in something more definite than terms of pure idealism or sentimentalism. He asks to know the facts and insists upon having the bearing of these facts upon his pro-

duction. Does not that represent, as accurately as any of us can, an answer to the question of where the employer is at today?

A Few Guideposts

In what direction are we going? Well, I shall have to modify my statement that perhaps I knew where we were going, and say that we know some of the guideposts along the road we are going and we can pick them up one by one. The first guidepost, and the one that hits us squarely in the face, is that we have neglected and forgotten and misapplied, the real character of the physician's profession when we tried to induct it into industry. That vital and difficult subject of medical ethics, I cannot pretend to master. At some pains, however, I have dug out at least two signposts in it and when either of them is neglected you have side-tracked your position and lost your way. The first and most vital one is the insurance of a personal relationship with his patient. His profession, it is true, is the application of science to the service of others, but I believe that the medical profession, as in the oldest days of story, is also the art of practice, as well as the application of science. If the physician does not maintain the personal relationship with his patient, he has violated what is most valuable in his hold on medical ethics and has lost his way for the time being.

Of the same nature is his protection of the confidence and trust of his patient. Whatever passes between himself and his patient is a privileged communication. It cannot be an employer's or the public's knowledge. Why? Because, if I see rightly, the art of practice is the giving of one's self and the receiving of one's self into confidence. If that becomes public knowledge, it violates this confidence. It violates every consideration of personality and of individuality; hence, the physician who betrays that confidence is outlawed by the individual patient. In trying to establish a different kind of relationship between physician and patient, he has been warped from a necessary restriction of his profession.

The second guidepost presents a

difficulty less important in its bearing on industrial medicine, and that is the relationship of the industrial physician to his fellow practitioner. I never knew a crowd of men so bent on protecting each other—so keen in realizing that his colleague's reputation is his true stock in trade; that when it is taken away the foundation on which he rests is gone.

I do not believe that the physician entering into industry needs to alter in any way what should be the relationship of the industrial physician to his fellow physicians. If this has happened, it is the fault of individuals and of jealousies arising out of a new plan rather than of any necessity of the situation.

Difficulty Unnecessary

What are the signs guiding the employee in the direction in which he is going? He also properly insists that the state of his health and the disease from which he may be suffering is not the proper knowledge of the employer and cannot belong to him. When he offers himself to the physician for treatment, the results of that examination must remain inviolate on the employer's part, just as on the physician's part. Violate that idea, and at once the basis is laid for suspicion of the medical department by the employees. Unless it is respected I do not believe you can have a proper medical department.

And what are the signposts that are guiding the employer? I shall have to take issue for a minute with a previous speaker. Industry can only produce something in so far as it produces goods at a profit. Industry, under the older conception, existed only to produce goods at a profit, but we are all conscious that a higher conception has come into the management of industry. But still, society holds us responsible for the employment of capital at a profit. Society, however, also insists more and more strenuously that we can only use that capital so long as we do not injure the community and our fellow men. Society is coming to insist, perhaps not quite so strenuously, but with unerring determination, that we shall not use that capital unless we use it for the promotion and upbuilding of the community in which we reside, and is not content to measure our responsibility by the easier task of whether we are damaging the community or not. When you come to apply the test, "Are you so using this trust so that it is working for the upbuilding of your fellow men and the

community?" there is coming home to the employer both through his own pride and an inexorable legal force, influences which make him study his problems as he never studied them before.

We will agree that all of these signposts have nothing really discouraging in them. They point clearly towards an attainable goal.

What the Load Is

Next, in passing these guideposts, what is the load that we have to carry? Perhaps it is because it was so clear in your minds of what items made up the load that they have not been touched upon, except in the most general terms. Let us run over them hastily. The cases that are already loaded into these vehicles are: (1) The examinations for employment; (2) the first aid treatment of all minor disabilities occurring within the plant; (3) the entire treatment of all industrial accidents; (4) a far more thorough examination and research into all of the production problems connected with health that are becoming more and more important to the industrial capacities of our plant; (5) the life extension work in which the enterprise of the Life Extension Institute of New York has led the way with such clearness of vision; and (6) finally, the medical administration of mutual benefit or fraternal associations. They especially have been a constant force for education in helping to carry all of the various parts of the program.

The Vehicle

If we have arrived at any conception of where we are, or in what direction we are going, and of what the load is, we must consider the kind of vehicle that is going to carry that load. We have tried two kinds of vehicles. The first was a failure. That was the part-time physician, the practising physician who was called into industry on a part time basis. Why did it fail? Because the private physician had only a very vague idea of the problems of industry. He could not approach them with experience. He could not for one moment get himself out of his idea of a personal relationship with his patients. It also failed because the part-time men were only partially trained in the use of the diagnostic facilities offered and were poorly equipped for the group task before them.

The other experiment, which is found in many plants, is the full-time physician, clearly recognizing his relations to the industry and his rela-

tions to the employee. It seems necessary for his success, so far as we have been able to observe it, that he shall say frankly, "I have no business with the bedside cases or with the serious cases of acute illness."

We must offer every facility for diagnosis and for consultation but, except in the treatment of ambulatory cases, our whole effort must be to give the actual care of acute illness to the family physician. That is the only possible way in such cases. It is the only way in which all of the parts of the treatment of the case can be covered. No one in industry has yet any conception of the possibility of taking on the whole load of medical treatment. As I look on it, it is impossible from either a social or an economic point of view.

There is a third vehicle—suggested by the valuable work that the Life Extension Institute has done—of an association of physicians offering their services to both employers and employees, combining in one cooperative association all the most highly developed diagnostic aids available, which probably would be beyond the reach of any single physician; often, by calling in a specialist in consultation for special cases, dividing the expense, which at present is a difficult matter to divide. But, on the whole, the part that can be charged to the employer is becoming plain. He must pay for the examinations for employment, for the cost of accidents, and for the most valuable work in research. He can afford to pay a large part of the burden of expense for capital equipment, but when it comes to the burden of individual treatment of sickness, that must be borne by the individual patient. But you industrial physicians can make it possible for the day laborer to have every diagnostic facility and to have within his call specialists for consultation. When you have done that, you will have solved the relationship with the individual, as you have already solved the relationship with the industry.

This, of course, is not at all a new idea. You will find parts of it at work in many fields. You will find it in many clinics. But, this I insist upon: that while the man, or association of men, who are going to tie up with industry must retain in all their integrity their individual relations with their patients, they must study the problems of industry and meet them with sincerity, with intelligence, and with knowledge. There is the vehicle. It may be an imperfect one, but, at any rate, many members of this association have the vision and

are daily working out its difficulties and removing the obstacles that have seemed impossible to overcome at the start.

The Goal

We have heard of late just one note of pessimism. Is the goal worth while? Surely, if we know in what direction we are going and have the means of transportation, we are going to arrive, if the goal is worth while. I cannot take seriously the idea that after these seven years there should have been any discussion as to whether the goal is worth while. Certainly the goal of the engineer in human efficiency, which some of the doctors took to themselves as a title, was an impracticable one and they were quite unprepared to maintain

and carry that journey out. Let us, as doctors of medicine, forget forever the title of "human engineer," and let us return to the oldest term of the profession and become "physicians to industry" with absolute insistence upon personality in the service that we are rendering. Then many of the clouds around that goal will clear away and open up a brighter vision.

To some degree the stability of these United States depends upon the effectiveness of your contribution of medicine to the industrial organization. The elements of this organization become daily more clear to us. It is impossible to doubt that the industrial physician has made a great contribution to this job of bringing about better relations between the em-

ployer and the employed; that should he go, industry will have lost what it never can replace in other ways. Having achieved that vision, the battle is half won.

To the members of the Association of Employment Managers, I will say that if they can express to every individual in their ranks the assurance that there is a way out—that through education, through self-expression, through representation, and through physical upbuilding, they have the means within their knowledge of finding the way out—the problem is at least in the way of solution. In the finding of that way out, nothing can be more effective in raising the physical and mental tone of employees than the instruments in the hands of the industrial physician.

Work of the National Industrial Conference Board

Shall the Community Assign to Industry the Public Health Concerns of the Worker?

By C. C. BURLINGAME, M.D., CHENEY BROS., SOUTH MANCHESTER, CONN.

THE Conference Board of Physicians in Industry, formed seven years ago, has recently allied itself with the National Industrial Conference Board as its official advisor on medical problems in industry.

Five years ago another board of physicians who were devoting their entire time to industrial medicine was formed in New England and became the New England Conference of Industrial Physicians, of which organization I serve as Chairman.

The men in the Conference Board of Physicians in Industry came from all parts of the country and grouped themselves together to solve industrial medical problems. In New England thirty so-called full time men banded together for a like purpose, and I feel sure that an expression from all these men would indicate that the greatest importance attaches to the problem of where the physician in industry is going. Certainly none of them would say that the goal of industrial medicine is not worth while, though they may still be in doubt as to the best vehicle for reaching the goal. But, when all is said, the physician is essentially an individualist and must give of his personality to his people. If, after sinking his personality in the industry and becoming in reality a part of it, he then finds that he is out of the industry,—that his services are dis-

continued because of hard times or other causes, it is no wonder that the physician may be discouraged. It is not money—the dollars and cents lost—nor the position sacrificed, but his opportunity for service in a chosen field and the fact that he may feel he has lost his chance to be worth something to society, that makes him uneasy and discouraged. It was for service in society that he was born and educated.

The young medical man of today can afford to take the chance while the problem is being worked out, and he is still young. But can he fifteen or twenty years from now take a chance on seeing the excellent work, the best efforts in his life, thrown over in a period of business depression, and he a man without a job and with doubtful opportunity for service? This is the question asked by men in industry who are trying to get good medical men to help solve the problem of medicine in industry.

The Question of Value

We industrial physicians very glibly say that industrial medicine pays, but, personally, I do not know that anyone could prove it. I have compiled many figures but cannot say that they afford mathematical proof that industrial medicine pays. Certainly those massed figures do not convince those who are paying

the bills of the fact, but it is by rather obvious logic and by the review of individual cases that we can demonstrate to the employer that to supply industrial medical service is good business policy.

There is no executive who maintains a medical department who cannot tell some other employer about some case which, if it had not been handled by the company doctor, would have cost a great deal of money and several lives. These things are all true and it is good for the doctor to tell the executive about it. It is part of the executive's education, and medical men all know how necessary it is to give these executives some education on these lines and in the realm of medical ethics.

Men have related to the Conference the difficulty encountered in training officials to realize that there is such a thing as medical ethics and that every time the medical director finds a nice juicy bit of scandal the executives are not entitled to know about it. When the executives asked, "What is the matter with Smith?" it is somewhat of a task to tell them politely that it is none of their business. They have to learn that they must look to the doctor to deliver an end result,—a man or woman better able to stay on the job. It is hard to get the executive to realize that, with the doctor in the pay of the company, the

doctor owes his first allegiance to the patient; he must serve the patient first, last, and all the time, and that in so doing, he best serves his employer.

I suggested as a topic for discussion, "What do we think of our employer?" This was meant in a spirit of kindness, because, after all, we must admit when we get together, that we find it easier to educate the employer in medical ethics, and to educate him as to what the position of the medical man in industry should be, than it is to educate the medical profession as a whole.

Our task is to bring the physicians generally to recognize the fact that industrial medicine is worth while, and to ask for it the support of the American Medical Association, and the support of every other ethical medical body.

The non-professional people may be assured that we physicians have not lost confidence in industrial medicine. It presents its own problems, which we are going to solve; and we are going to make the sacrifices that are necessary to solve them. But there remains open the question whether the thing which we call the industrial medical problem will be

solved in industry and in the pay of and under the direction of industry, or as a community problem, to be met by the community and by the people as a whole. Whatever group assumes the responsibility for the problem, we are going to stay with it until it is solved.

At the close of the evening, Mr. Charles A. Andrews addressed the assembly as follows: It is, of course, an unusual and supposedly improper thing for a toastmaster, who is a mere layman, to undertake to add anything to the program after it is completed. Just one thought that I should like to leave with you, for what it is worth—and you will conclude for yourself whether it is worth anything or not. We have had references made to the problems to be solved by the physician in industry; and we have had references to the problems to be solved by the industrial manager with relation to medical practice in his industry. These two problems are, to a considerable extent separate; one for one group, and one for the other group; but there is one problem which can be solved only by the management and the physician together, that is the

problem of bringing the employees to understand that medicine in industry is not something that is being put across on them by the management, for the sole purpose of getting more hours of efficient work out of them, and thus to increase production and profits. If the employees think that this is the whole of the story and its incentive, however wise the management, however scientific and efficient and helpful the physician, we will not get very far in establishing in industry a medical practice with the ideals we have advocated. There is much more than science to it and much more than the application of science. Some way or other, doctors and managers must together make it so clear that it cannot be misunderstood that there is something in the program other than a further exploitation of the employee for the sake of profit, that there is in the program a further and better thing—abundant hope that medicine in industry has come to stay and to be of increasing usefulness, contributing to the daily contentment and well being of the men and women in industry in order that they may be better men and women and more useful citizens.

St. Louis Southwestern Railway Medical Service

By A. E. CHACE, M.D., CHIEF SURGEON, ST. LOUIS, Mo.

THE scope of the work of a medical department serving a railway company is only partly indicated by tabulated figures, but some idea of the service of the St. Louis Southwestern lines may be gained from the statement that during 1920, a total of 14,067 cases—1,527 of them personal injury cases—were cared for by the medical department. Nearly all were men, and in the care of these cases over thirty-one thousand days of hospital care were given, and 26,267 prescriptions written and filled; 123 major and 297 minor operations were done; 260 Wassermann tests made; 6,030 dressings of wounds done; 34,341 venereal treatments given; 615 roentgenographic examinations made; 2,174 dental treatments were involved; 4,191 laboratory examinations by the pathologist and many more by the surgeons were performed.

From these figures it will be seen that the ten thousand employees make free use of the medical service. The graphs in Figure 1 indicate the yearly fluctuations.

Founded in June, 1887, this is one of the older medical departments in

industry. First occupying an altered house as hospital at Tyler, Texas, the work grew until, for several reasons, it became necessary in 1904 to build the present hospital at Texarkana, Ark.

The St. Louis Southwestern Hospital can now care for eighty white, sixty-three negro, and eight contagious patients—a total of 151 patients. When the nurse's home is completed, permitting the rooms on

The hospital of the St. Louis Southwestern Railway, located at Texarkana, Ark.

Fig. 1. Graphs showing fluctuations of service from year to year.

the third floor of the hospital, now occupied by nurses and staff, to be used for patients, the capacity will be increased to two hundred.

The main hospital is composed of four buildings, three of which are connected by covered bridges—the hospital for white patients, the negro and surgical pavilions. The heating plant and work-shop adjoin the negro hospital. Cases of contagion are handled in four small frame buildings about two hundred yards from the main hospital. About thirty acres of park and pasture, a modern dairy barn, a horse and vehicle stable, two pump houses, a frame cottage, and a brick railway station complete the major equipment.

In the first story of the surgical pavilion, ground level, are the bath rooms, receiving ward, and surgeon's office. On the second story are the main operating room, sterilizing room, wash room, minor operating, dressing, and dental operating rooms.

On the first story of the hospital for white patients are two venereal wards, orderlies' room, x-ray and dark rooms, game and reading room, three dining rooms, kitchen, pantry and three store rooms. On the second floor are the wards, each containing from four to ten beds, laboratory, pharmacy, diet kitchen, service rooms, and three offices. One of these is the hospital office, another is for the superintendent of nurses, and a third for the medical department of the railway. The third floor is now occupied by nurses and staff.

The negro hospital contains six wards for colored patients, one for Mexicans, a dining room, dressing, and examination room, and the usual service rooms.

An electric elevator, centrally located, with a five by eight foot car, serves the three buildings. Screened galleries on the south side of the white, and east side of the negro hospital, will accommodate twenty-five

patients, and it is seldom unpleasant in this climate to sleep out of doors.

The locations of the fifteen emergency stations and the location of the eighty local surgeons are shown on the map (Fig. 2). The emergency stations consist of part time, salaried surgeons who maintain the offices, small first aid equipment in shops and round houses, arrangements with nearby hospitals for temporary care, and contract with pharmacies at these points. Here employees receive temporary care until moved to the St. Louis Southwestern Hospital, or they receive treatment for ambulatory cases.

First-Aid Materials

All baggage cars are supplied with cots, or United States army stretchers. The cots, especially, are frequently stolen, so it occasionally happens that, at the time most needed, they are not to be found. The stretchers, clearly marked in large letters, do not seem to be so magnetic.

Small packets are always on hand for distribution upon request of conductors or engineers. It is not the policy of this department, however, to encourage the surplus or wide distribution of first-aid material for use by half-trained laymen. This would not only be wasteful, but cause suffering and economic loss far in excess of the occasional benefit. Proper labels clearly outline the type and indicate the proper use of this material. Thus the equipment of this department consists of: (1) a centrally located hospital, (2) fifteen emergency stations, (3) eighty local surgeons, maintaining offices, and (4) the proper distribution of first aid material.

Personnel of Department

At the fifteen emergency stations, thirty-four division, assistant and associate surgeons and specialists are carried on a salary basis for part time work. The salary is based upon the amount of work done, taking the average over a period of years.

The main hospital is composed of four buildings. The heating plant and workshop adjoin the negro hospital.

The laboratory handled during the year reported 4,191 pathological examinations, not including special work done by the surgeons.

The eighty local surgeons are under contract on a fee basis. The fees average a little less than the charge in private practice; in some localities equal to these charges, in other towns less. All surgeons receive an annual pass.

The hospital personnel consists of a chief surgeon, internist, one house surgeon, one assistant house surgeon, one assistant house surgeon in charge of venereal diseases, an eye specialist, ear, nose and throat specialist, consulting anesthetist, four consulting surgeons, a pathologist, a roentgenologist, a dentist, a superintendent of nurses, a night supervisor of nurses, an operating room nurse, chief clerk, hospital clerk, an accountant, a house keeper, an engineer, a carpenter, a steward, student nurses, cooks, orderlies, milkman, etc.

The chief surgeon is a full time officer of the railroad, is held responsible for the entire medical department, appoints all surgeons, reports directly to the president, and is expected to perform all major operations at the hospital, except when out of town the consulting surgeons operate.

Management of Department

The funds necessary for the support of the medical department are derived from two sources. The railway company appropriates money for the capital charges, and makes up any deficit in the running expense. The employees voluntarily contribute, by monthly deductions, an amount which under normal conditions is expected to cover operating expenses. These deductions are made on the basis of the amount earned during the month.

Earnings	Monthly Payment
\$ 5-\$ 50\$0.40
50- 1000.60
100- 1990.70
200 and over1.00

The rules governing benefits define very definite services. Thus all illness or injury resulting from vicious habits and unlawful acts is excluded,

except venereal diseases. A limit of six months, with exceptions at the discretion of the chief surgeon, is fixed. All benefits terminate when an employee leaves the service, is discharged, or is excluded for cause. An injured man is entitled to treatment anywhere on the railroad until he can be moved to the St. Louis Southwestern Hospital, or, if that be impossible to one of the other fifteen hospitals with which the railroad has arrangements for the care of its employees. A sick employee must consult a salaried surgeon, known as Division Surgeon, Assistant, Associate Division Surgeon, or Specialist. Such surgeons are located at the fifteen emergency stations, where an employee may also have prescriptions filled free of cost at the company pharmacies. All employees too ill to work are expected to come to the St. Louis Southwestern Hospital if, in the judgment of the division surgeon, he can be safely moved. To avoid imposition, the ill or injured employee, except in

case of emergency, must obtain from his foreman a certificate, known as a red-cross certificate, to the effect that he is a bonifide employee and has had a deduction made on his last month's pay. This red-cross certificate entitles the employee to consultation and treatment by a salaried surgeon at emergency stations, to a pass to the St. Louis Southwestern Hospital, and to treatment in the hospital.

Local surgeons are appointed solely for the purpose of handling injury cases for first-aid care only.

Division and associate surgeons, their assistants and specialists—eye, ear, nose and throat—care for the major portion of the line work.

A sanitary engineer, reporting directly to the president, with a corps of assistants, has charge of such work as malaria control, water supplies, sanitation and inspection of restaurants, toilets, dining cars, stations and other railroad property.

A superintendent of safety, reporting to the vice-president, in charge

Fig. 2. Eighty local surgeons maintain offices at the points indicated and the location of the fifteen emergency stations is given.

The capacity of the hospital, now 151 patients, will soon be increased to 200, and a home for nurses will be added.

of operation, undertakes to minimize the hazards both on the line and in the shops.

The Legal Department has only one definite relation with the Medical Department. At the time of injury, the first surgeon to attend the employee, makes out a report in duplicate stating the nature of the injury and the probable disability. Both are sent to the chief surgeon, who forwards one copy to the Legal Department. A weekly report of the progress of hospital cases is also made. No information is supplied by the Medical Department which could be construed as a breach of a privileged communication. The only definite relation therefore is the proper one of protecting the railroad against illegal imposition.

Types of Work

Examination of applicants for employment is a complex. It involves careful job analysis, the application of employment psychology, estimation of the moral risk, searching physical examination, intricate records, salutary and sympathetic advice to the applicant, a follow-up system, and a summarized report. The forms used on this railroad represent a beginning, not an end product, of the present tendency toward complexity.

Re-examination of employees is done every three months for food handlers. Never has such an examination been made without finding at least one case of communicable dis-

ease. For employees in train, yard and engine service, re-examination, up to the present time, has been limited to those who appear to their superior officials to require such re-examination. I believe we should have a stated interval.

The care of injury cases has been touched upon. It is the policy of this company to give these men the best first-aid care possible to obtain, to transport them quickly to the most efficient hospital, and if possible to care for them in our own institution until recovery is complete.

In general, slight medical and surgical cases are cared for at the emergency stations, more serious or protracted cases at the St. Louis Southwestern Hospital.

Venereal cases are given free care at our own hospital only. These cases, during the infections stage, are admitted under quarantine, required to wear muslin pajama suits to facilitate control, and reported by name to

Dental work is free to all patients who come to the hospital, whether for this treatment or in connection with other illness.

the State Health Officer if quarantine is violated.

All dental work, except crowns, bridges, and false teeth, is free to employees who come to the hospital, whether for this treatment only or in connection with other illness.

Contagious diseases are not of course transported on the trains. Occasionally, diphtheria, smallpox, measles, etc., come into the hospital undiagnosed and receive free care in the isolation cabins. At emergency stations, salaried surgeons care for these cases for a limited time, and afterward cooperate with the health officer.

At the St. Louis Southwestern Hospital, the work is carried out under the plan familiar to all as group practice. Minor illness is looked upon in the light of future possibilities, and due care taken to determine the exact condition.

This medical department is in the stage of transition from the better class of medical and surgical work in

The equipment is provided to supply that better class of medical and surgical treatment now called for in industry.

industry to the highly technical combination which we all hope will be better appreciated by all industry in the near future.

Industrial Tuberculosis and Dust

Three important studies made in the United States during the last decade on the absolute and proportionate ratio of the death rate from industrial tuberculosis and on the relations which exist in different industries between mortality due to tuberculosis and that due to other causes are analyzed in the *International Labour Review* of February, 1921.

In England numerous statistics are available which indicate that in many industrial employments high tuberculosis ratios are associated with high tuberculosis rates. In Sheffield for 1910, for example, it was found that the mortality from pulmonary tuberculosis among grinders was 14.8 per thousand for the age of 18 and over, a very high figure compared with that of 2.7 for all other workers, of the age of 20 and over. The corresponding death rate from other causes was 15.1 per thousand for grinders and 13.7 for other workers. Certain industries have specific influence on the development of industrial tuberculosis. There seems to be a heavy incidence among those in which the industrial dust is made up of crystalline rock. Silicosis dust is at the base of miner's phthisis and is probably the general factor in tuberculosis among ax grinders, although steel dust probably is important.

Methods to determine the content of dust atmosphere and various prophylactic measures are discussed and standards to be established. Standards, however, are only tentative and should be revised according to industrial circumstances. The discussion is based upon the work of C.-E. A. Winslow and Leonard Greenburg, which appeared in the *Journal of Industrial Hygiene*, January, 1921.

Roentgenographic examinations during the twelve months ending in January, 1921, numbered 615.

Advertise Prone Pressure Resuscitation*

The "One Best Way" for Safety Should Be Universalized

BY CHARLES A. LAUFFER, M.D., MEDICAL DIRECTOR, WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY, EAST PITTSBURGH, PA.

PROF. E. A. SCHAFER, chairman of the Committee appointed in 1890 by the Royal Medical and Chirurgical Society of London, read a paper on the "Prone Pressure Method" in Chicago, 1908, before the Section on Surgery of the American Medical Association. The conclusions reached by Prof. Schafer are that "a pressure method is best, and that such a method is more efficient with the patient in a prone position, and with the pressure applied vertically over the lowest ribs." To this method Prof. Schafer gave the name of "the prone pressure method."

Even before Prof. Schafer's address in Chicago in 1908, his method was known and employed in this country. When emergencies arise, a multiplicity of methods of resuscitation leads to confusion. The need of adopting some method as the standard was sensed by the National Electric Light Association, whose successive commissions have been epochal in standardizing the prone pressure method of artificial respiration. Leading surgeons and physiologists, industrial physicians, and engineers have labored together on these commissions, with the result that the prone pressure method emerged supreme. It is declared by these authoritative commissions of the National Electric Light Association to be the best manual method, and to be superior to all commercial mechanical apparatus yet devised for giving artificial respiration.

Adopted But Not Used

Successes attending the employment of the prone pressure method, within and without the industries, have contributed to its quite universal acceptance. Safety committees of industrial groups comprising five million men have accepted the prone pressure method, and it is being extensively taught to intelligent employees within the industries. In short, the prone pressure method is the standard method, but it appears that it has not been sufficiently advertised.

Complaints reached the Safety Committee of the National Electric Light Association that physicians summoned on emergency calls are sometimes quite unfamiliar with the prone pressure method of artificial respiration. Such physicians would doubtless employ it, and assist those administering it, if the prone pressure method were better advertised. First aid instruction emphasizes the slogan: "Summon the physician." Additional assistance is expected from the physician summoned, not negation of the aid being supplied by laymen, trained in prone pressure procedure.

Picture this situation: Artificial respiration by the prone pressure method is being given a victim of electric shock by laymen well qualified in prone pressure. The physician on his arrival says prone pressure is no good, and orders them to stop it. In some cases, it is reliably reported, where the advice of the physician has been ignored in this respect, the artificial respiration has succeeded in restoring the patient; obeying the physician, however, makes it a coroner's case.

Such being the case, what is to be done about it? Is it not incumbent on industrial physicians, who have long employed prone pressure, and who have faith in it, better to advertise the method?

The best technic in giving prone pressure should reach all the physicians of the country through their medical journals. Prone pressure should be in the medical textbooks, so that the coming generation of practitioners will be versed therein. It should be in the school books. There should be better illustrations, and better instructions, in the manuals of the Boy Scouts, the Y. M. C. A., the Red Cross, the National Safety Council, and kindred organizations, devoted to the cause of safety, so that the art of prone pressure may be generally promulgated.

Firemen, policemen, and ambulance drivers everywhere should know how to give prone pressure. Many avoidable deaths occur owing to the interference of policemen in various cities. Policemen often will not permit quali-

fied laymen to administer artificial respiration, and by the time a physician is summoned the patient is dead, resulting in a situation that is tragic. Teaching the prone pressure method of artificial respiration to laymen within as well as without the ranks of industry, is a public safety measure in which industrial physicians have a patriotic duty to perform.

Advantages Enumerated

The relative advantages of the prone pressure method are too well known to require much comment, but a brief summary may be in order.

(1) Prone pressure is a one-man method. It is easy to learn and easy to apply. Under proper technic, one person can keep it up an hour without undue fatigue. A single operator, alone and unassisted, with no devices other than his hands, and with no assistance from any other instructed person, can successfully resuscitate the victim of accidental drowning, gas asphyxiation, electric shock, or other condition requiring immediate efforts at artificial respiration.

(2) No time is lost hunting up mechanical devices, in which the persons applying them may be unskilled, or which may not be in working condition. As to this latter point, I some time ago ascertained that a certain street railway company had twelve devices, not one of which was in working condition, and that they did not have twelve men competent to operate them. Such apparatus deteriorates, the rubber parts break and leak, so that unless they are maintained in first class condition by daily or weekly inspection, and the replacement of parts made by competent mechanics, they are not serviceable. It may be stated that this company has since scrapped all these devices, and now relies entirely on prone pressure. The tide has set in against mechanical devices for artificial respiration.

(3) Even if a serviceable mechanical device can be obtained, it may not be immediately available. It is unfair to the prone pressure method to say that the mechanical device has resuscitated the victim, when the victim has been kept going by the manual method, and is practically resuscitated.

*Read before the Ninth Annual Meeting of the American Association of Industrial Physicians, Boston, Mass., June 6-7, 1921.

1. Schafer, E. A.: The Prone Pressure Method, *Jour. A. M. A.*, 1908, li, No. 10.

With thumbs turned out, fingers parallel, pressure is made on floating ribs.

tated before mechanical devices reach the scene.

(4) The manual method elevates the diaphragm, pumps venous blood from the liver and splanchnic area to the heart—which is empty in electric shock—and, by distending the heart and blood vessels by the massage of these parts, it aids in the restoration of circulation. As is well known, in electric shock the heart action may be suspended before respiration is arrested, consequently the manual method, by stimulating cardiac function, holds out the greater prospect of restoring animation in the victims of electric shock.

(5) The use of mechanical devices of the bellows type requires a degree of pressure to inflate the lungs, and a degree of suction to empty the lungs, that is incompatible with normal physiologic breathing. In other words, the mechanical devices are the more liable to do violence to the pulmonary tissues than are manual methods. The manual methods more closely imitate nature.

(6) The water in the lungs encountered in drowning, and the edema of the lungs encountered in electric shock, and occasionally observed in asphyxiation by gases, require that the patient be in a prone position. The prone position not only facilitates the removal of liquids from the lungs and air passages, but it permits the tongue to gravitate forward, thereby making it possible for one man, alone and unassisted, to resuscitate a comrade in distress.

When Method Fails

The lack of success sometimes attributed to prone pressure may arise from faulty technic. Especially is attention drawn to the necessity of "placing the hands on the lowest ribs," with the thumbs turned out, fingers parallel, and touching; and making vertical pressure from the shoulders, keeping the arms straight.

The friends of prone pressure have unwittingly damaged their cause in the eyes of many conscientious physicians by the publication of placards and pamphlets illustrating pressure made on the fixed ribs of the thorax.

Pressure must be made on the floating ribs alone. "Vertical pressure on the lowest ribs" is the *sine qua non* of the prone pressure method.

It is in order to study a mounted skeleton, placing it in the prone position, kneeling, and applying the hands, so as to ascertain what expanse of ribs the hands cover. When the fingers are spread, and the thumbs lie parallel to each other, or their tips are turned toward each other, which some of the prone pressure pictures unfortunately present as the proper technic. Some hands will cover six ribs. Consequently, this must be considered a wrong posture for the hands, as only the lowest two ribs are movable.

With the thumbs turned well out, at right angles to the spine, the fingers parallel and touching each other, the expanse of the hands can be confined to the floating ribs. This is obviously the correct position for the hands. This posture of the hands obviates the lost energy which is incident to pressure on the fixed ribs of the chest.

Turning the thumbs outward also wraps the radius around the ulna, thus preventing bending of the arms at the elbow. With the arms thus held straight, vertical pressure from the shoulders is exerted on the outer ends of the lowest ribs.

Leverage With Little Effort

When pressure is made in this manner, near the outer ends of the floating ribs, the maximum leverage with the least effort is obtained. The organs below the diaphragm are shoved up against the diaphragm, thereby compressing and emptying the lungs.

Compression is gradual and occupies three seconds, release of pressure is more sudden and covers two seconds. Each act of artificial respiration thus requires five seconds. Twelve times per minute is the recommended rate of operation.

After a dozen years of successful achievement, the prone pressure method has, without the assistance of press agents, come into vogue as the manual method of choice in giving artificial respiration. We believe the

time is ripe for entering on educational propaganda to better advertise this method to the medical profession and to the public. To this end we should agree on the more minute details of the technic, so as to obviate as far as possible all contention within our own ranks, before advertising prone pressure on a more universal scale.

Acting as an authorized spokesman for the National Electric Light Association, and representing the Conference Board of Physicians in Industry, of whose Committee on Prone Pressure Propaganda I am chairman, I very earnestly solicit the aid and co-operation of my colleagues of the American Association of Industrial Physicians and Surgeons, as to the best means of advertising prone pressure.

It is our belief that this organization should approve by resolution the prone pressure method, and should adopt appropriate means of advertising it in an effective manner to all physicians in the country, particularly those within or near the industries.

Especially should a committee of this organization standardize on an illustration. The pictorial presentation of prone pressure tells practically the whole story. It reveals: (1) The patient's position; (2) the operator's position; and (3) the position of the operator's hands.

Rock forward to exert pressure; backwards to release pressure; arms straight; weight from shoulders—fifty words, more or less, tell how to do it. This Organization has an opportunity for constructive work in standardizing instruction in prone pressure in conjunction with other organizations in this field.

Divergence of Technic

The divergence of technic in the the minor points of procedure need not occasion controversy. Some of these variations of nonessentials are the following:

(1) Some extend both arms on the ground. Others extend the right arm and fold left forearm under the head. The latter method we oppose, because it affords less facility for gravity to drain the air passages.

(2) When pressure is released, our present practice is to remit pressure, yet retain the hands in position. Others remove the hands. When hands are entirely removed, some operators do not readily recover the correct position with sufficient facility to insure efficient artificial respiration.

(3) Some rules for prone pressure

feature traction on the tongue. Others virtually ignore the tongue, allowing it to remain in the mouth, if the jaws are locked, or letting it gravitate out, if the patient is relaxed.

(4) Some, unfortunately, make the victim of electric shock walk as soon as he is revived. Others carry him on a stretcher, put him in bed and treat him with the same care given

cases of traumatic or surgical shock.

(5) As to the urgency of immediate efforts, there should be no divergence of practice. With respiration suspended, the patient should be given artificial respiration at once, before he is transported to a hospital. An interval of waiting may prove fatal; hence, if conveyed in an ambulance, the prone pressure should be given *en route*.

supervise the work of the local examining physicians.

(7) *Desirability of physical examinations of children during school and pre-school period.*—Many of the physical defects found in children applying for work permits could easily have been discovered and cured, or prevented altogether, by proper examination and treatment during the child's school life, or even earlier. The committee therefore urges the necessity for the provision of adequate facilities for medical examination and treatment of all children of school and pre-school age.

(8) *Need of study by local administrative and medical officers of occupations in which children are employed and of their effect upon health.*—Occupations in which children are likely to be employed should be made the subject of special study for the purpose of ascertaining their physical requirements, and their effect upon the health and development of the growing child. The examining physician should be authorized and required to visit periodically industrial establishments and to familiarize himself with conditions of employment and with the various health hazards of industry.

(9) *Need of authoritative scientific investigation.*—The committee recognizes the impossibility of formulating definite physical standards for children in industry which will be complete and finally authoritative without a great deal of further scientific study of the effect of different kinds of work upon the health and physique of the adolescent child.

Research is especially needed with reference to:

- (a) The rate of growth and development of children employed in different occupations and industries as compared with children not in industry.
- (b) Morbidity among children employed in different occupations and industries as compared with children not in industry.
- (c) Mortality among children employed in different occupations and industries as compared with children not in industry.
- (d) Fatigue in children employed in different occupations and industries.
- (e) Effect of employment in specific occupations at different stages of physiological development upon the growth and health of—(1) Normal children. (2) Children with certain physical defects (such as compensated cardiac disease or with orthopedic defects) or with a personal or family history indicating predisposition to certain diseases.
- (f) Effect of employment in specific occupations upon the menstrual function and pelvic organs of adolescent girls and young women.
- (g) Types of work desirable for: (1) Children and young persons with some mental defect who, nevertheless, are able to fulfill the educational requirements necessary to obtain em-

Standard for Child Workers

THE child who goes to work between fourteen and eighteen years of age is in need of special protection if he is to arrive at maturity with good health and a vigorous, well developed body, but the means of protecting the child worker have been limited. A preliminary report, Conference Series No. 4, Bulletin Publication No. 79, just issued, by the Committee appointed by the Children's Bureau of the United States Department of Labor to formulate standards of normal development and sound health for the use of physicians in examining children entering employment and children at work contains a digest of types of legislation, standards of administration, points to be covered and the methods to be employed in examination, and the following formulation of standards:

(1) *Age minimum for entrance into industry.*—The minimum age for the entrance of children into industry should be not younger than sixteen years. Since it is recognized that the physiological and psychological readjustments incident to pubescence (which in the vast majority of cases are not completed until the sixteenth year) determine a period of general instability which makes great and special demands upon the vitality of the child, it is of paramount importance that he should be protected during this period from the physical and nervous strain which the entrance into industry inevitably entails. The committee recognizes the fact that pubescence may occur early or may be very greatly delayed, and is convinced that the longer it is delayed the stronger is the indication of a physical stage during which it is highly inappropriate to subject the child to the strains of industry.

(2) *Physical Minimum for entrance into industry.*—No child between the ages of sixteen and eighteen should be permitted to go to work who is not of normal development for his age, of sound health and physically fit for the work at which he is to be employed.

(3) *Physical examinations for children entering industry.*—The physical fitness of children entering industry should be determined by means of a thorough physical examination con-

ducted by a public medical officer appointed for this purpose. Where possible all examinations should be made without clothing. Before such a physical examination is made, the child should present a definite promise of employment in writing from his intended employer, stating the specific occupation at which he is to be employed.

(4) *Re-examination for children changing occupations.*—The employment certificate should not be given to the child, but sent by mail to the employer. When a child leaves the specific employment for which the certificate was issued, the employer should return the permit to the issuing officer by mail. With each change of employer another examination should be made before the child is again permitted to work, the mode of procedure to be the same as in the issuance of the original permit. When a child is transferred to any occupation in the same establishment differing in its physical demands and hazards from those common to the occupation for which the permit has been issued, this must be communicated by the employer to the issuing officer in writing, and a new physical examination of the child made and a new certificate issued.

(5) *Periodical re-examinations for all working children.*—All employed children up to the age of eighteen should have at least one yearly physical examination, to be made by a public medical officer appointed for this purpose. Whenever in the judgment of the medical examiner more frequent examinations are desirable, the child should be ordered to report at stated intervals for this purpose. These examinations should take place either in the certificate issuing office, in the continuation school, or in the establishment in which the child is employed.

(6) *Centralized control of methods of examination.*—In order to insure uniformity in methods of examination in each State the State labor or other department administering the child labor law should have authority to make rules and regulations relative to methods of examination and qualifications of examining physicians, to prescribe record forms, and to require reports with reference to examinations made. Each such department should employ one or more physicians qualified in industrial hygiene, who shall be authorized and required to

ployment certificate. (2) Children and young persons who are suffering from certain physical handicaps, such as the partially disabled child and the child with seriously impaired vision or hearing.

(h) Industries and occupations in which children are customarily employed with special reference to health hazards.

Material for at least the greater number of such studies might effectively and economically be secured from the records of examinations made in the public schools and in connection with the issuance of employment certificates in states where re-examinations are required. It is, therefore, urged that all such exam-

inations be scientifically and thoroughly made and that methods and record forms be standardized so as to be statistically comparable.

(10) *Certain tentative minimum standards obtainable from results of scientific research already available.*—While recognizing the necessity of further study, the committee is of the opinion that the results of scientific research already available, together with the experience acquired in the administration of laws prescribing physical requirements for admission to industry, permit the recommendation at the present time of certain tentative minimum standards. The acceptance of these standards will aid materially in safeguarding the physical welfare of the child obliged to enter industry before reaching his full development.

Recent Compensation Decisions

THE International and Great Northern Railway Employees Hospital Association, which was formed to provide medical and surgical treatment for its members and to include all the employees of the International and Great Northern Railway Company, was in a recent case held not to be an insurance company, but a mutual benefit association, and its contracts with its several members cannot be regarded or construed as contracts of insurance.

A rule of the Association was held not to authorize the treatment of a member away from the line of the railway, or by other than one of the physicians of the association, and a member who was taken suddenly sick in St. Louis, Mo., while in the performance of his duties as an employee of the railway, was not entitled to receive from the Association money expended for medical services, although under his contract of employment with the railroad he was required to pay monthly dues to the Association.

In the course of his employment the employee started from Houston to Chicago, but became seriously sick, with typhoid fever, and arrived at St. Louis delirious. He was there taken to a hospital and treated but at no time was in a condition to be carried to the defendant's hospital at Palestine, Texas. He claimed that the amount of his expenses, and charges for nurses, physicians, surgeons, medicines, hospital fees, etc., came to \$1,193.10; that he was too ill to communicate with the chief surgeon of the hospital; that the officials of the railway operating for the United

States Railroad Administration knew of his sickness, as well as members of the defendant's trustees and its chief surgeon; and that the defendant was a mutual benefit, health and accident insurance association. The defendant answered by general demurrer and general denial. The trial in the court below without a jury resulted in judgment in favor of the plaintiff for the sum of \$1,193.10.

There was no dispute as to the facts, the only controversy being over the construction of the charter, rules and by-laws of the defendant association. *International & G. N. Ry. Employees Hospital Assn. v. Bell*, (Tex. Ct. of Civil Appeals, June 3, 1920) 224 SW 309.

WHERE an employee killed himself while possessed of an uncontrollable insane impulse or while in delirium of frenzy . . . such insanity or delirium having been caused by pain resulting from diseased condition caused by the electric shock which he received in the course of his employment, his widow was properly awarded compensation . . . *Lupper v. Baldwin Locomotive Works*, Superior Court of Pennsylvania, February 14, 1921, 112 Atl. 458.)

A WORKMAN who had long been afflicted with periodical recurrences of epilepsy was seized with an epileptic fit in the course of his employment in a refining plant, but such epileptic fit was not traceable to his work, nor did his employment contribute in any measure toward bringing on such affliction. During his epileptic seizure the workman became unconscious and fell

against some hot pipes and severely burned his back. Held, that the accident and consequent injury did not arise out of his employment but out of his affliction, and compensation for his injury cannot be awarded against his employer.—*Cox v. Kansas City Refining Company*, Superior Court of Kansas, February 12, 1921, 195 Pac. 863.

A DECLARATION in an action for a servant's death, alleging that the defendant employer undertook to furnish hospital and medical attention, and breached that duty by turning the servant out of the hospital too soon and leaving him without attention, was held to state a cause of action, the defendant being under duty to use some degree of care in discharging the voluntary undertaking.—*Karababis v. E. I. Du Pont de Nemours & Co.*, Superior Court of Appeals of Virginia, January 20, 1921, 105 SE 75.)

THE workmen's Compensation Law should be construed fairly, indeed liberally, in favor of the employees.

Injury resulting from an assault by a workman upon a fellow workman while the latter is engaged in the work of the master is an "accidental personal injury arising out of and in the course of employment" within the meaning of the term as used in Sec. 1 (Art. 2) of the Workmen's Compensation Act.

The test of liability under the Workmen's Compensation Law for injuries arising out of and in the course of an employment is, not the master's dereliction, whether his own or that of his representatives, acting within the scope of their authority, but is the relation of the service to the injury, of the employment to the risk.

While waiting at the bottom of the shaft for a cage to arrive, the petitioner asked the assistant mine foreman and a fellow employee, where the cage was, saying that he (the petitioner) wanted the cage to go out of the mine. Whereupon the foreman becoming angry, applied an ugly epithet to the petitioner, adding, "Why don't you go up the air shaft?" Upon the petitioner resenting the insult, the latter picked up a scantling and struck petitioner over the head, knocking him down and crushing and breaking his skull so severely that he remained unconscious for some time.—*Stasmos v. State Industrial Commission et al*, Sup. Ct. of Okla., February 8, 1921, 195 Pac 762.)

Practical Methods of Fatigue Elimination*

Allied Societies as Well as Organized Labor Unite With Engineers to Eliminate Unnecessary Fatigue.

By FRANK B. GILBRETH, CHAIRMAN, COMMITTEE FOR THE ELIMINATION OF UNNECESSARY FATIGUE, SOCIETY OF INDUSTRIAL ENGINEERS, MONTCLAIR, N. J.

THE first work of those who advocate and practise fatigue study is to arouse a general interest in this study, and especially in the elimination of unnecessary fatigue. The Committee of the Society of Industrial Engineers assigned to this work has succeeded in arousing such interest.

This Committee is international in its scope, and consists both of members and non-members of the Society. There will soon be a hundred members. The number is not limited. The committee aims to consist of members from every line of activity that can profitably cooperate, either in the theory or the practice of fatigue elimination.

Personnel of Committee

The personnel of our Committee is interesting. We have research workers in medicine, in psychology, in physiology, and in psychiatry; economists and statisticians; representatives of the Department of Labor, national and state; of personnel work; of the American Posture League; educators, representatives of sister societies; an expert in visual education who has also had many years experience in the army and as director of a famous museum; editors, writers, and an advertising expert. It is scarcely necessary, today, to say that we have women as well as men members of the Committee. Two of our as yet small number of foreign members are women.

Being a committee of a society of engineers, a larger number of our members are engineers than belong to any other profession. Some are members of the Engineering Foundation. Some are teachers of engineering—professors, deans, and, in one case, a president of a scientific college. Several are editors. The large majority of our engineering members are members of this Society, although the other great engineering societies are well represented. Many are engaged in consulting engineering, many belonging to the special group

installing scientific management in various plants. Our foreign members represent many of the countries of Europe. We have also a Canadian member, and there will be added within the next month several representatives from Asia.

The Committee has suffered a great loss during the last fortnight through the death of Mr. Lester G. French, editor of the *Journal* of the American Society of Mechanical Engineers. Through his devoted work on the *Journal*, Mr. French has for years been an influence in engineering progress, and in arousing interest in the movement for the elimination of unnecessary fatigue. His accessibility, cordiality and warm-heartedness have been such a factor in the hospitality of the Engineers Building that many of us feel that he can never completely be replaced. It should be the pleasure of this committee to pass a resolution telling of our appreciation of the loss that we have sustained in the passing of Mr. French, and expressing our sympathy to his family.

As for the work that the Committee has accomplished, we can perhaps point to some tangible achievements. Several of our members have done work for fatigue on Fatigue Elimination Day, the first Monday in December. Professor Blessing held the first Fatigue Elimination Day at college at Swarthmore and his program has served as a stimulus and suggestion for others. The most continued and enduring work on Fatigue Elimination Day in England has been done by Professor Henry J. Spooner, also a member of our committee, director of the Polytechnic School of Engineering, London. Professor Spooner holds yearly a competition in which his students write essays on the subject of fatigue, and has not only aroused much interest, but sustained it and maintained his work ever since he started.

Mr. James F. Butterworth has done much pioneer work in disseminating information regarding fatigue elimination throughout the British Empire.

Our members have also written articles on fatigue, conducted researches in fatigue, and introduced fatigue elimination methods and de-

vices in plants. In fact, in most cases the membership of the committee has stood for real constructive accurate work in the elimination of fatigue.

The intangible results of the work of our Committee—the by-products as we might say—have been much more far reaching in their effects than the direct products. The subject of fatigue has become one of universal interest. More and more the literature and the advertising throughout the world shows *thinking* along the lines of fatigue elimination. Therefore, as a committee, and as members of the Society of Industrial Engineers, we may congratulate ourselves that our campaign of arousing interest in fatigue has been successful and profitable. We must not, however, be satisfied with what has already been done, because the small field that we have been able to cover is as nothing compared with the work that we must accomplish in this line.

The subject of this report is "Practical Methods of Fatigue Elimination." If we are to do worth while work, we must insist first of all that the work of our own Committee is practical. There are some very definite suggestions to be made along this line. First, the Committee must be enlarged. We should have at least one representative in every country of the world, preferably more, the number covering representatives in each field that directly affects fatigue. In this country we should have a representative in each section of this society, and in each industry and in each trade. It is especially necessary that we have at once more representatives of allied societies, and some representatives of organized labor. It is suggested along these lines that each person present, connected with the Association, whether a member of the committee or not, hand in to the chairman a list of names of people in any country who would be appropriate members of this Committee. It is suggested that the name and address be given, also the line of life work in which the person suggested is an expert or is interested, and some suggestion of the type of work that he might best be asked to do.

*A report delivered before the Society of Industrial Engineers, Milwaukee, Wis., April 29, 1921.

While we are increasing our Committee, we must not fail to utilize the material that we have already enlisted. The membership of our Committee should be carefully studied, in order to see what possibilities we have, and the work of the Committee should be functionalized. At this early stage of the investigation of fatigue, which is a comparatively new subject to many, it has not seemed practical to appoint sub-committees, but this subject is one open for discussion at today's meeting. The work of the Committee itself should certainly be functionalized, even though the members are not assigned to particular functions, because the field is so large, in fact, unlimited, and the membership so small, comparatively speaking, that each member may well handle many or all of the functions in his own vicinity and it is not the intention to limit activity merely to the function assigned. However, we as advocates of functional management must see that through utilizing the specialties of our membership, we can make the most profitable advances.

Collaboration Called For

The Committee is remiss in failing to turn in to the chairman reports or records of work accomplished or suggestions of possible work. This is probably due to the fact that all members of the Committee are busy with other important work. It should be possible, with a group as large as ours, covering as large a field geographically and in the various kinds of world's work, to obtain at once a complete bibliography, a record of current happenings in the field of fatigue, and an enormous body of suggestions, yet the chairman receives comparatively few from members of the Committee on the subject of fatigue except those that are in reply to notices or other letters from him, but this will not deter him, for he promises to continue to push forward the movement for dissemination of information concerning the elimination of unnecessary fatigue until it has been preached and practised in all parts of this semi-civilized world.

Because of the nature of the Committee and great distance separating the members, it is impossible to hold many meetings at which a large percentage of the membership is present, nor is this necessary. Exchange of all data received will not be difficult. The *Bulletin* of the Society of Industrial Engineers acts as an admirable circulation medium for information, and its business manager is an in-

terested and cooperative friend to the Fatigue Elimination Committee.

Fatigue Elimination Day should this current year be marked in some special way by each member of the committee. Professor Spooner's paper presented at this meeting contains an admirable suggestion that each Fatigue Elimination Day be given a specific subject. We believe that the usefulness of data will be greater if it is so divided and grouped. The two papers which come from abroad are both on the subject of the "Elimination of Noise," and Professor Spooner suggests that this topic be made the subject for Fatigue Elimination Day for 1921. We should be glad to have the action of the committee on this suggestion.

A review of our Committee shows very plainly that we have ample material for speakers upon the subject of fatigue. The Committee should be canvassed, in order to discover who are willing to speak, and we shall serve as a sort of speakers' bureau for any interested in the subject.

It should be another duty of the Committee to stimulate interest in fatigue by seeing that the subject is introduced on the platform of every convention of this and other societies. The subject itself is so wide in its scope, since it concerns every member of the community and is equally important in the fields of production, selling, finance, schools and home life, that there is no excuse for not making fatigue a feature at every meeting.

Permanent Fatigue Exhibit

We might as well also consider the beginning of a permanent fatigue exhibit, which might be sent from one convention to another to arouse interest in the subject. The "Laziest man's table," which is shown for the first time at this convention, is important only as a simple, easily made device, designed to make its user and observer think in terms of fatigue elimination. It is most important at this stage in our development that we emphasize the point that fatigue elimination affects every member of the community, and that much of it is so simple that no training is required to do it, and we should have a large number of simple thought-stimulating exhibits available.

This society should insist that Congress afford room in some of the unused buildings at Washington for a fatigue museum, which was started by one of the members of our Committee, the former head of the American Medical Museum, whose work in the army deserves Congressional

recognition. I refer to Col. W. O. Owen, of the Medical Corps (retired). His work was well under way when he was automatically retired, having reached the age limit in the Army.

The Society of Industrial Engineers has offered a place in its exhibition, at each convention, to the Fatigue Committee. We have not availed ourselves of this space as we should. It is brought to the attention of the committee that it is our duty to ask for and to utilize a far larger space at the next convention, and to furnish Mr. Dent at once material for the Bulletin urging students, inventors, manufacturers, and users of fatigue eliminating devices or methods to place them in this exhibition.

It is also a duty of this committee to plan at this session for our next session at the next convention of the Industrial Engineers. Definite suggestions for program and speakers should be made at this time. On the slips recently sent you with the notice of this meeting was a space for suggestions on interesting speakers. We desire to thank those who filled in the spaces, and to assure them that their information will be utilized and is much appreciated. Concerning the program today, it is interesting to note that the two papers that have been sent in are from abroad—one from Professor Spooner, the other from Mr. J. S. Heoghiemetra, a friend of Professor Volmer, the eminent economist who is a member of our committee and a pioneer worker in the great movement of dissemination of knowledge regarding fatigue elimination, management, and standardization that is taking place in Holland.

The leaders of the discussion, Mr. Segur and Mr. Shephard, represent two branches of our committee—the engineer-installer and engineer-teacher. Mr. Segur has been interested in and has done exceptionally fine work in fatigue study and motion study for years. Professor Shephard is conducting a most interesting laboratory investigation in fatigue with his students. Unfortunately he is not here to present his subject, but has promised to submit a discussion in writing. Other members of our committee have signified a willingness to talk, and will be called upon immediately after the discussion is opened.

Work in the Future

Finally, as to plans for future development, all of our work so far has lain along the lines of arousing interest and surveying present practice and showing what has been actually done in fatigue elimination and its

study. The next step in our development, for the entire process is carefully laid out to the final super-standardization which should be the work of our committee—lies in gathering together material suitable to be incorporated into standards. Fatigue elimination standards and their exhibition where they will be available to all must be our next goal. *Standardization* is a word of paramount importance today, although not so much—in some instances, at least—in this country at the present moment, as in the countries abroad; this in spite of the fact that in total, this country has done the most. Two recent trips, including an intensive inquiry into con-

ditions in four countries in Europe show that everywhere is coming a realization that the stability which is essential to progress will be secured quickest by standardizing first those things concerning which there is no dispute, and among these fatigue occupies the first place.

From our data already accumulated and from the papers presented today and succeeding papers, we should now proceed to make simple preliminary fatigue standards that may be submitted to our committee, to our society, to the engineering profession, and to the world at large to add to the comfort and happiness of all workers.

the energy and half the money to increasing the power of man over Nature, which would increase the total result which is to be divided among the members of the community, instead of devoting all their energies to seeing how the relatively petty amount that we already produce is to be divided among the producers."

He did not believe that the mere expenditure of money, the mere growth of laboratories and the mere multiplication of students were going to produce a larger crop of men of genius. But the amount of work which was not epoch making but which was absolutely required if great discoveries were to be made could bring admirable fruits both to knowledge and to industry, and for that organization and money were required. It was a great grief to him that the poverty from which all were suffering had compelled a very reluctant treasury to cut down the sum at their disposal. No money was better spent than that on scientific research. No money gave a greater spiritual return, and none was going to give a greater pecuniary return. The Universities of Cambridge or Edinburgh, of which he happened to be Chancellor, were both groaning under a particular disability in the matter. He was often surprised that the imagination of great magnates was not stimulated by the idea that they could really add to the wealth of the whole world by encouraging industrial research. He could not help thinking that it was in part due to an imperfect apprehension of the real facts of the case and to that fatal desire to see the immediate results of any effort that might be made. As regards the material side it was apt to be forgotten that a discovery did not profit merely the company or capitalist who first turned it to account, but it might touch the lives of every dweller in every civilized country, and it was folly to say that that was a low material view of things. The hope he had for the world was that the growth of science and invention would give comfort and leisure where at present discomfort and labor were the only means of producing. That was the ideal of progress which he thought held out the most hope for the future.

A Disinterested Public

Perhaps, the part of Mr. Balfour's speech most worthy of attention was that in which he referred to the indifference of the public to science of any kind and to research work of any description. It is a failing of human

Science Has Served Industry

BY OUR LONDON CORRESPONDENT

WHAT science has done for industry cannot be over-estimated. The prosperity of industry without the aid of scientific methods is impossible and possibly that is the reason why American millionaires with remarkable foresight have given money lavishly in the aid of science and especially of medical science. British rich men are backward in assisting the progress of science, perhaps because they do not understand that in helping science, and medical research, in particular they are really benefiting their country and themselves.

By means of science industrialism reaps its rich harvest which is often rendered possible by a new development of science. Then the captain of industry can become the philanthropist, as so many successful business men in America do become, and by his munificence enable science to open other highways to wealth and assure progress in many directions. However, whatever may be the cause, the lamentable fact remains that money in large sums is not forthcoming in this country to help science in any of its aspects, and in this respect conditions have been considerably worse since the war. Those who used to give, on account of burdensome taxation, and consequently straitened means, cannot do so now, and the newly rich are not sufficiently impressed with their responsibilities or duties to become philanthropists on a large scale. Thus, in this country science languishes. Occasionally there are rifts in the clouds as, for instance when a

few weeks ago an Institute of Physics was opened.

Physics is the most fundamental of all sciences, and therefore its efficient teaching is essential to a proper understanding of medical science. That this is so, is made evident by the establishment of chairs of physics in several of the medical schools of this country. Consequently, the launching of an Institute of Physics, although strangely belated, was a great event in the British scientific world. It was aptly described by Mr. Balfour as "a red letter day in the history of British Science."

Physics Fundamental

Mr. Balfour in an eloquent speech at the inaugural meeting said in part that physics was "the Science of Sciences" and it was certainly surprising that this country, which had not been behind any country in the world in the great advances it had made in physical knowledge, had had to wait until 1921 for the foundation of an Institute of Physics. He was afraid he could claim no more than that he was helping on to the best of his ability the admirable work done by the Council of Industrial Research. The public knew little about that work. The public seldom did know much about the things which most deeply concerned them. Industrial research was one of the things which most deeply concerned them. He confessed that when he saw great industrial disputes going on about the distribution of the results of industry he could not help thinking to himself "Why do not they devote half

nature that that which the ordinary man does not understand he treats with contempt, ignores. Science is quite out of his depth and, as he can see no immediate result for himself, he is prone to regard it as a fad and does not wish to be taxed in the slightest to advance it. He does not realize the progress that industry has made and will make by the aid of science, and he requires education on these points. The contempt through ignorance that the rank and file of the taxpayers have for medical science has recently been strikingly exemplified by the manner in which they have opposed all the schemes formulated by the Ministry of Health for the benefit

of the health of the nation. They do not seem to understand that good health is the greatest asset of any nation, and that the nation which is the healthiest, other things being fairly equal, is inevitably the most prosperous. It is obviously of the utmost importance that industrial work should be done under the most healthful conditions, and in order that this may be brought about scientific methods must be introduced. The establishment of an Institute of Physics in Great Britain marks a long step forward on the path which leads to industrial progress because such progress cannot be made without the assistance of science.

Malingering a Normal Reaction

That malingering is a perfectly normal reaction of simple-minded persons is the opinion expressed by Dr. Tom A. Williams in the April issue of the *American Journal of Insanity*. It is not necessarily a mark of disease. When an individual has not developed mentally to the point where he appreciates the points of behavior which adds good to the community, to condone his attitude, the continuance or the simulation of a disease is maintained as a defense reaction.

The task of the neurologist requires an insight to prevent the acceptance at face value of all the psycho-pathological phenomena the malingering case presents and from being unfair to those who do present a mental or physical disorder. The malingerer is particularly susceptible to suggestion, hence the value of skeptical and strong handed observation in influencing the false attitude of the malingerer.

The genesis of the mental reaction of malingering is often to be found in environmental conditions of childhood, the crisis calling it forth merely serving to exaggerate characteristic tendencies.

Dr. Williams goes on to discuss the fabrications indulged in by perverse mythomaniacs, disease simulation, the functional disorders due to emotion. The examiner's task in such cases is complicated. He must not ignore real symptoms, and must avoid creating suspicion on the part of the patient. Definite tests are possible in given complaints.

As to the legal and moral responsibility, some declare that the more experienced is the observer in the study of mental abnormalities and of the insane, the less inclined is he to give a diagnosis of malingering. There is the real danger on the other hand in the tendency of many alienists to excuse the behavior of every one on the basis of the deviation found. It is precisely those persons who have the least self-control whom it is a menace to relieve of the external controlling principle embodied in the fear of punishment. It must not be forgotten that there is a degree of disordered function which renders it impossible for an individual to respond to continuous stimuli from without, however powerful. Men who reach this degree of neurological deficiency must of course be removed from the ranks for treatment. The keenest discrimination is called for in the differential diagnosis of such cases.

Letter from the Secretary

THE American Association of Industrial Physicians and Surgeons was organized in the early part of 1916, by Drs. A. M. Harvey, H. E. Mock, C. G. Farnum, J. E. Stubb, W. E. Post, T. R. Crowder, and S. M. McCurdy, to promote medical work among the industries and the more general understanding as to the benefits derived therefrom, and to unite into one organization members of the medical profession specializing in industrial medicine and surgery for their mutual advancement in the practice of their profession.

The first annual meeting was held in Detroit at Hotel Cadillac on June 12, 1916, during the week of the meeting of the American Medical Association. The Association is now five years old and has a membership of approximately five hundred members from industries in all parts of the country. The association has become an established thing and from now on its growth should be both rapid and substantial. It is perhaps fitting to quote a telegram sent by Dr. H. E. Mock to the officers of the Association during the week of the Boston meeting:

Regret exceedingly illness prevents my participation in annual meeting of our grand Association. Disappointment is keen. Dreams and ideals advanced first meeting Detroit five years ago have now become realities. Nation awake to industrial waste in human life. The next five years hold greater possibilities than every before. Greetings to all.

With this message as a stimulus can not this Association during the coming year increase its membership twofold? It is conservatively estimated that there are in the United

States somewhere near two thousand eligible physicians, giving either part or whole time to the industries of the nation, that workers may be kept fit for their tasks. The Secretary cannot extend the membership; nor can a membership committee accomplish it. It devolves upon the entire membership to bring such a result about. Every member can surely secure one or two additional members. The dues are not excessive and in return a member secures a subscription to the *NATION'S HEALTH*, our official journal. It is hoped that in addition other services can be made possible and that in the end a good five dollars worth will be forthcoming. Added numbers to our membership will strengthen our position greatly and assist us materially in advancing the cause of industrial medicine.

It is with reluctance that the Secretary announces the resignation from the Association of Dr. Charles A. Lauffer, former medical director of the Westinghouse Electric and Manufacturing Company. Dr. Lauffer is leaving the field of industrial medicine. He does so with keen regrets but for good and sufficient reasons. Dr. Lauffer has been most active in the field of industrial medicine, contributing numerous papers at various meetings and has been regarded among our first leaders in the field.

The Secretary's page will welcome at all times notes of interest from the membership which should be passed on through this medium. We want to make this page a live one in every respect. It is only possible by co-operation.

INSTITUTIONAL HEALTH

The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents

Physical Development of Midshipmen

Physical Defect is Regarded as a Sign of Weakness to be Overcome by Definite Effort.

By EVERETT B. TAYLOR, LIEUTENANT, MEDICAL CORPS, UNITED STATES NAVY, ANNAPOLIS, MD.

THE essential difference between the Naval Academy and other institutions of this country lies in the fact that it prepares its men directly for positions as officers in the United States Navy. It requires for entrance a thorough physical as well as mental examination based on a standard selected minimum average for age. After the applicant has passed this examination, his condition speaks for itself.

It becomes the duty of those who control and direct the institution to employ every means in their power to train and develop these young men, in order that they may be better fitted to carry out their important life mission. Executive officers attached to the United States Naval Academy are selected from those whose abilities are of that character that qualify them for this duty. Medical officers are also assigned, and their activities are synchronized with the executive department. Skilled instructors are chosen from both service and civilian life for didactic work. All of these are aided and augmented by the work of physical instructors and trainers whose duty it is to build up and maintain at its highest rate of efficiency the condition of the midshipmen. As in any other enterprise, it is only through the synergistic action of those concerned that the best and the desired results are obtained.

As this article is dedicated to the physical side of the midshipmen's life, it will be necessary in great measure to lose sight of the executive standpoint, and look at it more from the angle of the medical man, who is the one concerned with sickness and

health, and largely with the physical condition of the midshipmen. The administrative and medical heads work together, so that each has cognizance of the other, and what is done is through recommendations and action with full consideration of all concerned in order that the best results may be obtained. The medical officers come in contact with the midshipmen in all their activities, and are so disposed as to cover every field.

As has been said, the first important duty in connection with the young men is to determine the fitness of the applicant for entrance. Each applicant must pass a prescribed physical examination, and when found qualified, being robust and of good constitution, he formally enters the Academy. Quoting from the regulations governing the admission of candidates to the Naval Academy:

Candidates are required to be of good moral character, physically sound, well formed, and of robust constitution. Any one of the following conditions will be sufficient to

cause the rejection of the candidate, viz:

- (a) Feeble constitution, inherited or acquired.
- (b) Retarded development.
- (c) Impaired general health.
- (d) Decided cachexia, diathesis, or predisposition; anemia, from malaria or from intestinal parasites, as hookworm.

- (e) Any disease, deformity, or result of injury that would impair efficiency; such as, (ea) Weak or disordered intellect; (eb) Cutaneous or communicable disease; (ec) Unnatural curvature of the spine, torticollis, or other deformity; (ed) Inefficiency of either of the extremities or large articulations from any cause; (ef) Epilepsy or other convulsions within five years.

- (f) Impaired vision, disease of the organs of vision, imperfect color sense; visual acuteness must be normal, i.e., 20/20 for each eye without the aid of glasses. There should be no deviation from this standard.

- (g) Impaired hearing or disease of either ear. The organs of hearing, both conductive apparatus (outer and middle ear) and the percipient apparatus (internal ear), must be free from disease. In testing the hearing

Entrance to Rotunda, Bancroft Hall, United States Naval Academy.

The Chapel, United States Naval Academy, Annapolis, Md.

of the candidate, the voice, the ticking of a watch, and, if practicable, Politzer's acoumeter shall be employed.

The voice is a more reliable method of determining the acuteness of hearing than the ticking of an ordinary watch, as it allows for variations in hearing, with the modifications produced by changes in pitch and tone. Hearing in each ear must be normally acute to the spoken and whispered voice. In examining the acuteness of hearing with the voice, one ear of the candidate should be closed while the other ear is being examined, and his eyes should be covered to prevent lip reading. The ticking of an ordinary watch should be heard a distance of 40 inches.

(h) Chronic nasal catarrh, ozena, polypi, or great enlargement of the tonsils.

(i) Impediment of speech to such an extent as to impair efficiency in the performance of duty.

(k) Disease of heart or lungs or decided indications of liability to cardiac or pulmonary affections.

(l) Hernia, complete or incomplete, undescended testis.

(m) Varicocele, sarcocele, hydrocele, stricture, fistula, hemorrhoids, or varicose veins of the lower limbs.

(n) Phimosis, and diseases of the genito-urinary organs.

(o) Ingrowing nails, bunions, cross or hammer toes, flat feet, or other deformity of feet.

(p) Loss of many teeth, or teeth generally unsound. Marked overbite, or lack of occlusion of jaws. There should be at least eight opposing molars, two on each side in each jaw. All defective teeth should have permanent fillings. Much time can be saved by previous attention to this requirement.

Attention will also be paid to the stature of the candidate, and no one manifestly under size for his age will be received at the Academy. The height of the candidates for admission shall not be less than 5 feet 2 inches between the ages of 16 and 18 years, and not less than 5 feet 4 inches between the ages of 18 and 20 years; and the minimum weight at 16 years of age shall be 111 pounds, with an increase of not less than three pounds for each additional year, or fraction of a year over one half. Any marked deviation in the height and weight relative to the age of the candidate will add materially to the consideration for rejection.

The decision of the medical board, especially ordered by the department for the examination of candidates for entrance to the Naval Academy, upon the physical qualifications for admission, will be final.

Medical officers are required to examine physically any candidate for the Naval Academy who may appear with a letter from a member of Congress so requesting. Special attention will be given to the following defects or disabilities: Flat feet, defective vision or hearing, heart or lung trouble, and disease of the kidneys. The candidate should be informed of the result of the examination and a copy of the report of examination shall be forwarded to the Member of Congress concerned and a duplicate report to the Bureau of Navigation. Each examination report shall show the name of the Senator or Representative requesting the examination.

Medical examiners should bear in mind that the primary object of this examination is to eliminate those who are obviously disqualified, rather than to give assurance to any candidates that they will subsequently pass the

official examination. For example, candidates who appear with rapid heart action, without organic lesion, shall be informed that unless such condition is temporary they will probably be rejected. Candidates having varicocele, hemorrhoids, varicose veins, or other minor surgical defects of remediable nature should be informed that they will probably be rejected unless these defects are corrected by operation.

In every border line case where the examiner himself is uncertain as to the outcome, candidates and Members of Congress should be clearly informed that the case is a doubtful one.

In the examination of candidates for admission as midshipmen into the Naval Academy, medical officers shall be governed substantially by the instructions contained in the Navy Regulations relating to the physical examination of recruits.

A high standard of physical excellence is essential in the cases of all candidates presenting themselves for admission to the Academy, and medical officers should always keep in view the fact that the future physical efficiency of officers of the Navy will depend largely upon the manner in which this important and exacting duty is performed by the board.

A careful urinary analysis shall be made in the case of every candidate undergoing examination. The urine shall be tested qualitatively and, if deemed necessary, quantitatively for sugar and albumin. Where albumin exists in appreciable quantity a microscopic examination shall be made. These examinations are carried out by a permanent medical board having as its head the Senior Medical Officer of the Station, who is director of all medical activities.

Immediately after entrance each midshipman of the entering class is given the "Strength Test," with the use of the Kellog Universal Dynamometer. When the Dynamometers were first installed here they were standardized by running off tests of more than one thousand midshipmen, and averages taken and designated according to the various heights—sixty-two inches being the minimum allowance. In this manner a standard Anthropometric Chart has been prepared and is used for all midshipmen. It contains in appropriate columns, according to height, the strength units required of each of the forty-two muscle groups tested, and shows the standard of strength required for midshipmen of the first or graduating class. An allowance of one inch, not to fall below the requirements for sixty-two inches in height, is made for the second class; two inches for the third, and three inches for the fourth class. Failure to attain the required number of strength points in any one muscle group constitutes a defect. A chart is made out for each man, with the defects noted in the proper column,

and this chart kept on file in the office of the gymnasium medical officer. Whenever a man's chart shows defects he is regarded as weak, and a course of exercises and physical training is prescribed for him. These exercises are designed to correct the weak muscles. After this course of training he returns for another test of these defective groups.

When the defects are corrected he is no longer regarded as weak and his chart is held over until the following year. If at the end of the year, however, he is still found defective, he must utilize a part of his September leave in bringing up these deficiencies. On the back of each chart is tabulated the corrective exercises for the defective muscles. Each muscle group is named, and opposite is designated the particular exercises and the type of apparatus for use in correcting its weaknesses. Each machine or piece of apparatus is numbered according to its place in the gymnasium, and these numbers are also included on the back of the chart, so that carrying out the exercises becomes much easier and more systematic.

Several methods of maintaining these charts have been used, but the one finally accepted and in use now, is that of running the strength points down in its column, then checking these against the column of points required in each case, and finally noting the deficiencies in the column alongside the first. This shows at a glance how the man stands; and as the deficiencies are worked off the results are designated in succeeding columns. For example, E. W. A.'s chart shows nine defects—right and left grip, right and left Latissimus dorsi, right and left foot flexor, right and left thigh flexor, and right leg extensor—taken in the early part of September. After a course of corrective exercises he came back in October of the same year and upon being reexamined in these deficient groups, he attained the required standard. Another method may be represented by that of R. R. A., who was given the "Strength Test" upon entering in the summer, and showed more than fifty per cent deficiencies—allowance being made of three inches for the fourth class. For this method of checkage the chart is lined out in somewhat the same manner as a fever chart. His initial test shows his unit curve largely below the standard line for his height. In October after returning to the Academy from the summer practice cruise, his next test was taken and showed his deficiency curve less than thirty per cent below normal—in other

An open air boxing class in action. The fundamentals of all sports are taught and particular attention is given to a graded improvement each year.

words shows a net improvement of approximately thirty per cent. His third test given in October of the following year shows less than five per cent deficiencies, or practically normal. In a very short additional time his chart is brought up to the standard.

There are numerous instances of this kind, some taking longer and some shorter periods of time to be brought to or above normal; but all pointing to the same consequence, i. e., all midshipmen with inferior muscular development or weakness, have shown decided improvement after taking the prescribed treatment in the form of corrective exercise and physical training; and practically all cases have been able to bring their deficiencies to normal. Of course it is not meant to infer that this is the final criterion of the midshipmen's physical qualifications, but it is of sufficient importance for the one in question to be held responsible for its finality. The charts furnish the desired and very important information as to the condition of the body as far as muscular strength and development is concerned, and furnishes an index of his condition throughout his stay at the Naval Academy and also as to the efficiency of the system used for his benefit.

Every educational institution recognizes the importance of having as large a list of athletic sports as possible for the benefit of its men, and every measure is taken for the promotion of their welfare along these lines. In the military school compulsory drills and formations are necessary, together with a certain amount of gymnasium and Swedish exercises. All institutions—the military more especially—have come to realize the advantage of having medical supervision in the realm of athletics. Men are examined here before going into

contests, and are checked up at various times, in order to avoid dangers and prevent detrimental conditions. No better example of the necessity of this can be cited than that of a midshipman on the wrestling team at this institution, who took part in a meet not long ago. This young man was wrestling at a certain weight, and was extremely desirous of training down to a weight considerably lower. To do this it would be necessary for him to reduce his weight fifteen pounds within the space of ten days. This he did by the process of weight reduction known to wrestlers and boxers. The outcome of his bout, however, was disastrous. He not only failed miserably to handle his opponent, but at the end of the bout he had to be assisted from the mat in an exhausted condition from which he recovered slowly, requiring careful nursing for several days.

This subject of overtraining cannot be emphasized too much. Suffice it to say that the man who overtrains takes his life in his hands. In college athletics there should be no effort made to train down more than five or six pounds with the idea of keeping the weight down. Even this should be done gradually, allowing plenty of time for accommodation of the various organs and parts of the body. Of course there are times when athletes lose considerable weight, especially at the beginning of a season—notably football. This however, is quickly regained, and the recovery serves as a gauge of his reactions. Many a bout has been lost to a professional boxer who has had to train down considerably in order to enter the ring at a specified weight. The result is a weakened condition. That being true, why should a much less experienced man risk his match and his life trying to reach a lower weight? There is no hesitancy in

Injuries resulting from track are mostly from falls or sprains.

saying that in the future at this institution measures will be taken to prevent midshipmen from "boiling down" their weight more than a certain amount. Overzealous trainers will be prohibited from carrying out this method of reduction.

Not long ago the president of one of the largest and foremost universities of this country asked how many men were engaged in athletics at this institution. Upon being informed that approximately eighteen hundred men participated in the various forms of sports last year, he was amazed, and expressed the earnest wish that as many of his own students could be interested in that way. During the past year about eighteen hundred of the two thousand enrolled at the Naval Academy took part in either authorized or class games. The following is a list of the more important sports indulged in:

Football	Boxing	Water Polo
Baseball	Wrestling	Lacrosse
Basketball	Gymnasium	Soccer
Track	Fencing	Crew
Tennis	Swimming	Racing

All of these with the exception of Soccer are represented by a Varsity team, and all with the exception of crew racing and fencing are contested by classes in addition. During the colder months when the indoor contests are at their height, the sport card is so full that it would be impossible for one to see all the events. Imagine such a condition as this: a basketball game in one building, immediately followed by boxing,

wrestling and gymnasium contests in another—all of the last three named being contested at the same time. Simultaneously, fencing and swimming contests are being carried on in still other parts of the same building. In the realm of Spring sports it frequently happens that lacrosse and baseball games are being held on one athletic field, a track meet on another, crew races on the water, and tennis matches on the courts.

It is agreed that physical culture in some form or other is necessary for the development of young people, making them stronger, healthier, and better morally. It is also conceded that these athletic contests develop a spirit of aggressiveness, self-reliance, courage and endurance, and cultivate a spirit of sportsmanship and ability to sustain hard knocks. There does not seem to be any reasonable doubt that men who have had athletic training in younger days would be the last to show the white feather in action. The spirit of do or die cultivated in athletic contests is of inestimable value as an asset for the men of our Navy. These would be the last to admit defeat, and would be the first in the face of disaster and hardship, pain and fatigue, to make a new and greater effort.

Some attention must be paid to the fact that many athletes suffer in later life for the strains they have put upon their systems while in the course of athletic training in their younger days. There is many a sad

figure seen walking into the doctor's office presenting the picture of one who has "gone bad" after leading a record-breaking career in college athletics. If the history is gone into carefully, it will be found that the majority of these cases are those who have led a very active athletic career while in school, and after leaving there have settled down into business life, making no effort to gradually change from a strenuous athletic existence to a quieter sedentary life. Consequently the hypertrophied heart becomes flabby, valves relax, leaks occur and a lack of accommodation manifests itself in an improperly supported circulation, giving us the above picture. This, however, has not proved the case with men who have gone out from the Naval Academy.

There are examples without number of officers of today's Navy, who have graduated from the Academy in years gone by, who are in as good physical condition as could be expected for their age and service. The secret of this lies in the fact that the Government requires that its officers and men keep physically fit at all times; and when they enter active service they do not settle down to a soft sedentary existence, but undertake measure regularly for the upkeep of their physical condition. As a check upon this, every officer is given a thorough physical examination once a year. During the year preceding this examination he is required to take daily exercise of at least one-half hour. Defects, then, would under this system be certain to crop out, and weaknesses would appear if present. All midshipmen are given an annual physical examination and those who fail to come up to the required standards, are recommended for rejection. In support of the above statements, a careful anthropometric study of officers of the Navy Post-Graduate School who had varying amounts of service, was made by Lieutenant S. B. Solhaug, Medical Corps, U. S. Navy. These officers he divided into two groups—first, those who were recent graduates of the Academy, and second, those who had five years active duty. The second group showed a greater percentage of deficiencies than the first, particularly in the dorsal, abdominal, and femoral groups of muscles. This furnishes convincing proof of the necessity of requiring officers and men to keep up their physical condition.

As to the harmful effects of athletics there is very little to be said. These are partly avoidable through

the aid of medical supervision, and have been brought down to a minimum at this institution. These conditions arise from excessive strain upon the heart and other organs, and may be avoided by eliminating the unfit, proper diet, training and exercise, and avoidance of overtraining. Sometimes unforeseen conditions result from indulging in violent exercise too soon after eating. With proper warning and training these may be eliminated entirely. The accidents that occur during contests and due directly to them, are almost entirely unavoidable, but can be minimized by the immediate removal of the contestant and application of proper treatment. No one should be allowed to remain in training too long, as a prolonged and vigorous course of training will produce injurious results. After a period of about four months the young athlete should be advised to break training for a time. It is a well known fact that even within this space of time the athlete may go "stale," and have to be removed from the training table until a sufficient improvement is brought about.

The injuries growing out of these athletic contests have been derived chiefly from football, lacrosse, and wrestling. They consist mostly of sprains, dislocations, fractures, lacerations and contusions—in order of frequency. During all contests at this institution, a doctor is to be found at the scene of activity with a kit for first-aid treatments, after which the injured are either sent to Sick Quarters or to the Naval Hospital, according to the severity of the case. Boxing and track contribute their quota of injuries, but no extremely serious accidents have occurred in the experience of the writer with the exception of one fatality resulting a few days after a boxing bout, due to secondary cerebral hemorrhage.

The gymnasium medical officer has adjoining his office a treatment room, called "Misery Hall," where there are numerous devices for baking, massage, and the application of heat, facilities for dressings, strappings and splints, and a high frequency machine with its modalities. The latter has been used with very gratifying results in the treatment of the contused muscles, especially those due to football. It has been found that these conditions yield more readily to the treatment by the D'Arsonval and Sinusoidal currents, combined with the preliminary symptomatic treatment in the beginning, than from any other.

As stated before there is a regular routine of compulsory exercises carried out, and each midshipman is required to qualify for each of the tests in each group as they are arranged. When he fails to qualify a red check is placed in the proper column against him, and carried there until he has made the grade. The entering class is given one hour of Swedish drill a day during the summer, and each member is taught to lead and command. During the academic year each battalion of the fourth class is given a week of gymnasium drill—consisting of five one-hour periods—every month; and twenty minutes of each of these periods are devoted to Swedish exercises. The third class is divided into two sections, each of which has one hour of gymnasium drill a week, twenty minutes of which is Swedish. Men out of any class who fail to qualify in any of the tests relative to these drills and exercises, as well as those who are deficient in the Dynamometer tests, are placed in a special gymnasium squad, and given one hour of Swedish movements each week in addition. Whenever it is found that a midshipman of the first or graduating class has failed to make the average for as many as five muscle groups, he is considered as not qualified physically.

There are a number of gymnasium tests which each midshipman is required to pass before he is considered up to the standard. These tests are graded as C, B, and A—the C test being required of all fourth classmen, B of all third classmen and A of all second classmen. These number four-

teen in all and run as follows:

- (1) Bar vault, height of shoulders, double take-off without run.
- (2) Standing broad jump, distance according to grade.
- (3) Running high jump, height according to grade.
- (4) Dips on parallel bars, number of times according to grade, without a swing.
- (5) Chins on horizontal bars, number of times according to grade, using any grip.
- (6) Rope climbing, climbing hand over hand.
- (7) Making fast on single rope, for all classes.
- (8) Short horse exercises, strides and vaults according to grades.
- (9) Throwing medicine ball, distances graded, right and left hand.
- (10) Mounting shelf without assistance, using any method.
- (11) Running 440 yards, outdoor and indoor.
- (12) Horizontal bar exercises.
- (13) Wall bar exercises.
- (14) Tumbling, forward and backward rolls, and cartwheels.

Each midshipman is required to know how to swim, and all must pass certain tests in this division. The first test is that of keeping above water for five minutes, demonstrating breast, side and back strokes. The next is that of swimming 120 yards in three minutes and thirty seconds, using the breast, side and back strokes, each for forty yards. Included in this test is diving into the water and raising an object from the bottom of the pool. The last test is that of swimming 160 yards in four minutes and thirty seconds, using the

Training for the wrestling team. Emphasis is placed on wrestling and boxing as a means of strengthening the body.

breast, side, back and either the Trudgeon or Crawl strokes, each for forty yards. Included in this test is approaching a drowning person and swimming with him twenty yards to a place of safety, and then demonstrating ability to properly apply methods of resuscitating the apparently drowned.

Besides these physical requirements there are tests in wrestling, boxing and sports in general. There are other tests given in command and leadership, small sword, saber and cane, and setting up exercises. Last but by no means least, comes the question of posture, or "brace." Posture is one of the most important considerations for any military man, and is a subject that is gone into very thoroughly. A treatise has been prepared and incorporated into booklet form for the use and instruction of midshipmen, and each must have this in his possession. It contains in condensed form the theory and practice of posture, both at attention and marching; and at the end there is a chart of errors showing the more common faults of posture and how they may be obviated. Also the booklet contains a compact list of setting-up exercises, which may be easily made use of as a daily routine.

As an integral part of the midshipman's course of instruction should be

In playing soccer there is unlimited opportunity for agility and grace.

mentioned the course in hygiene. As enacted by law the graduating class receives fourteen lectures during a term besides periods of extra and individual instruction in the gymnasium. This course includes personal and general hygiene, anatomy and physiology, preventable diseases—especially venereal, and the effects of alcohol and other narcotics. This

class is examined at the end of the term and held accountable for a passing mark. Regular lectures on personal and general hygiene, including venereal and other preventable diseases, are given to the entering class. Thus we see that no midshipmen goes out of the Academy without a knowledge of physiology and hygiene, and the dangers of venereal diseases. The course in hygiene is enhanced by the use of lantern slides and moving pictures. The lectures are illustrated as far as possible. For two years a special exhibit on Social Hygiene, under the auspices of the Sixth Division of the Bureau of Navigation, has been held for the benefit of all midshipmen, as well as for the entire personnel.

For handling the sick, a dispensary service and Sick Quarters are maintained in the main dormitory building of the midshipmen. This department consists of a large and well stocked dispensary, consulting room, dressing rooms, laboratory, sterilizing plant, dental offices, and a complete eye, ear, nose and throat outfit, including a dark room. A corps of doctors, dentists, an eye specialist, and a number of hospital corpsmen are on duty there. Ample quarters for bed patients are maintained in Sick Quarters adjoining the dispensary and on the sunny side of the building. These wards consist of from four to ten beds each. The minor diseases are treated here, while the more serious and prolonged ones are transferred to the Naval Hospital at Annapolis. As an example of the work done by the medical department, the statistics shown in Table I indicate the work of the past three years.

One Way of Building Up the Nation's Manhood

New Tastes, More Wholesome Interests, Resiliency in Physical Vigor, Result from Outdoor Activities

BY GEORGE J. FISHER, M.D., DEPUTY CHIEF SCOUT EXECUTIVE, BOY SCOUTS OF AMERICA, NEW YORK CITY

WE GLORY in the fact in America that we are rapidly decreasing the death rate. It is cause for gratification. Our large cities, like New York City, have made great strides in saving life and in warding off death to a later date. The fight with the grim specter is a winning battle. Young children have been the largest beneficiaries. Let us thank God for that. This is our first duty, and we are performing it well.

In the next place we have conquered many, and hope to conquer still more of the great filth diseases. Typhus bothers us now practically not at all. Typhoid, a terrible death scourge just two decades ago, is rapidly becoming rare. We have found the clue that gives us a grip on these grim destroyers. Then too, such pestilences as smallpox and, more recently, diphtheria, have gone their way. We have found the magic for giving the individual resisting power so that he can grin and defy these former victors over the destinies of man.

Now all this is heartening, encouraging, inspiring.

If only we can, with greater success, find a way of successfully combating the great respiratory diseases, for staying off the great epidemics of influenza, of eliminating pneumonia, it would prove a marvelous leap forward in human advancement.

Respiration Suffers

The breathing apparatus seems to suffer most in modern times. Indoor life is exacting a terrible penalty. Possibly the respiratory apparatus is most decadent. Modern civilization lays its hands heaviest upon these organs. Is it because they are too quiescent? Is this the penalty for sitting still too much? Is it because they lack the tonic of the out of doors?

Then too the organic diseases seem to still be rampant, heart, liver, kidneys, the digestive organs. Boards of health can not prevail with these. They are not due to communicable diseases. They are the result of the individual's own life and habits. They may be considered primarily the result of two things, namely, under-muscular exercise and over-eating.

One of the most fundamental problems of the present day is how to create and maintain in a city bred and city cramped populace the love and sufficient opportunity for rejuvenating life in the open. This scene was an inspiration to the Boy Scouts of New York City.

They are the penalties of a sedentary life. They are constantly referred to as the diseases of degeneration.

Now what is the remedy? The answer is that man must find a way of adapting himself to sedentary pursuits. He must retain those forms

of physical activity that are basal to health. There must be a happy balance between work and play. He must observe a proper rhythm between indoors and outdoors, between rest and work, between activity and inactivity.

The great progress which has char-

Results with the Boy Scouts in New York give further proof that the genial influence of sunshine and fresh air quickens the vital processes of respiration and circulation. The psychological condition is improved as well, and the body acquires a greater working capacity.

It is now well understood that only muscular activity, developing nervous reserve as the basis of endurance, can be relied upon to enable the organism in later life to withstand the increased nervous strain of maturity. Physical activity and manual training, nature study and other forms of observation, says Tyler, may develop intellectual power and keenness more efficiently than reading and spelling. We are only beginning to appreciate the importance of purposive play and work. The superiority of open air activities is appreciated in New York.

The stimulus of beauty is a beneficent thing, stilling discordant notes and bringing into ordered rhythm the disintegrating influences of congested city life.

acterized the growth in recreational activities is encouraging. There is increasing participation in sports and games. The summer vacation is becoming a national habit. Daylight Saving in the cities has prolonged the play period in the day's order.

But, here is a strange thing. With all our gymnasiums—and we should have more of them; with all our college sports—and I would not curtail them; with all our baseball and team games, we do not seem to be making headway so far as reducing the death rate over forty is concerned. What is the reason? My opinion is that our forms of physical recreation do not carry through far enough. The more strenuous games like baseball, football, and tennis, are given up at a time when men need physical stimulation. Golf is an exception.

For Men of Forty

Now the great need is for interest and participation in those forms of exercise which do carry through, which a man can carry on right through life, and which keep him full of life and enthusiasm.

And right here is where I feel the Boy Scout Movement is going to prove, and is proving, a great beneficent national service. This program is an out-of-doors program. It seeks to lure the boys and their leaders into the open; to acquaint them with the woods; to teach them the charms and attractions of the forests; to sleep in the open, blink at the stars, throw bridges across streams, signal from the mountain tops, know the trees, become intimately acquainted with the birds, track animals, photograph them in their natural haunts, hike across the hills, row and canoe and climb and hike.

What a transformation results from

a month's experience in the woods. Think of what would happen if every person in America practised this kind of a program, not only for a month

in the summer, but during the entire year through such activities as week-end camps, over-night hikes, or daily hikes. This is the heart of the Scout Program. It is giving men and boys a taste for the woods. It is developing habits of living which endure, which carry through, which become more permanent than any program heretofore devised. It lacks the extreme specialization which characterizes our athletics. It does not have the severe muscular and heart strain which is typical of some of our major sports. It consists of a large number of smaller efforts, carried over a larger period of time and in the open air.

Given a few million boys in this attractive program, and undoubtedly there will be a marked improvement in the health of the Nation. It is the kind of a program which a father can enjoy with his son, which an older man can participate in with the youth. It is America's best recreative program.

Deficiency Diseases

AMERICAN scientists are in the foreground in the impetus given to our understanding of dietetics and food values, and in the use of the diet in the prevention and cure of disease, according to Dr. Alfred C. Reed in the July *Scientific Monthly*. Old dicta in regard to diet have been reversed and our appreciation of dietary requirements for health has broadened from the mere consideration of energy requirements to include a proper number of calories of food, the suitable distribution of this total caloric requirement between carbohydrate, fat, and protein, a proper supply of mineral salts, a sufficient water intake as well as the accessory food factors.

Recent carefully directed investigation has thrown much light on the three groups of vitamins. It is now possible by special chemical procedures to concentrate and isolate vitamins of these three groups and definitely to associate dietary deficiencies with given disorders.

McCarrison's recent work caused him to conclude that in the treatment of disease it should be regarded as highly important to emphasize "the significance in practice of a study of the dietary history of the case, believing that bacterial agencies are often but weeds which flourish in soil made ready for them by dietary defects, and also, that in the fuller comprehension of the science of dietetics

we shall understand more perfectly the beginning of disease and its therapy."

Nutritional dangers lurk in the increasing use of food substitutes; in excessive utilization of meats and sweets, and subnormal use of vegetables, fruit, and dairy products. Racial, local, and individual aberrations of diet are vastly important from the angle of public health, from which it may be inferred that the science of dietetics promises to become ever more important in the treatment and prevention of disease, and as essential from the sanitary and public health point of view as for the individual man or woman.

Dr. Reed's article discusses at length the clinical pictures of scurvy, beriberi, pellagra, and such other deficiency diseases as xerophthalmia, war edema, war dropsy, or famine edema—well called by H. Gideon Wells "nutritional dropsy." The comparative pathology is traced, ranging from palsy, through dropsy, cardiac weakness and degeneration, nerve degenerations, spongy gums, hemorrhages, bone lesions, to the lesions at bone ends which are so notable a feature of rickets and often scurvy.

Warning is issued against commercial preparations of vitamins which are beginning to appear on the market, as under ordinary conditions of life natural foods should supply any present deficiency.

Vocational Training vs. Occupational Therapy

Vocational Training Occupies the Minds of the Tuberculous on an Ever Advancing Plane

By PHILIP KING BROWN, M.D., SAN FRANCISCO, CALIF.

TEN years experience with ergotherapy at Arequipa, a sanatorium for tuberculous wage-earning women, carried on as it has been under strict medical supervision and limited to certain hours of work a day, has developed the following principles:

(1) An occupation is unquestionably desirable for every patient, even when confined to bed, who is not in any way toxic and who does not show any bad effects from the occupation.

(2) The character of each line of work must be sufficiently engrossing to hold the patient's interest and should be carried on in the case of bed patients without undue use of arms and should produce no excitement such as might come from competition, in finishing work. Standard of quality, not speed, must govern the whole effort.

(3) Experience has taught us to put aside loom work. Even knitting and crocheting of the coarser kind is rather dangerous. Patients who can carry on this kind of work safely should make up a group by themselves because they belong to the class that are very nearly ready to be discharged.

(4) White needle work done out of doors has the disadvantage in being a strain upon the eyes unless the patient is protected by a green or black sunshade or umbrella and sometimes even an eyeshade. The same disadvantage holds about reading outdoors if the light is strong. Embroidery work, limited to certain hours, has never seemed to be a disadvantage to any patient who could work at all.

(5) The making of raffia baskets offers an occupation, but is rather a useless task even if the baskets are artistic productions and command a fancy price, for they are apt to give patients a wrong idea about values. Work of this kind, and with it we class most bead work, is no work for men and if it commands a sentimental value it has more a demoralizing than a helpful influence.

(6) Bookbinding, except of the coarser kind, is too heavy a work, both the handling of the press and the binding of the folded leaves has proved to be too much for the patients.

(7) In the same way even a pro-

Arequipa Sanatorium, Manor, Calif., where ergotherapy for tuberculous wage-earning women has been carried on for years under strict medical supervision.

fessional woodcarver with tuberculosis demonstrated to us that woodcarving was too heavy a kind of work. The making of string hammocks is open to the same objection that holds with knitting and loom work.

(8) The mending of the wicker chairs and the making of baskets with wet wicker, particularly the smaller baskets which can be hand painted and sold to florists, are excellent work for patients who are

without fever and who do not tire easily. The variety of form and color offers stimulating interest, and the market for such things makes the work profitable.

(9) Pottery, which was carried on with great success after years of struggle, is the best single occupation that we have found, because the heavy work is merely the mixing of the clay and can be done by hired labor, as can be the pressing of tiles.

The mending of wicker chairs and the making of baskets of wet wicker stimulates interest and a ready market makes the work profitable.

Views of the President on Public Health

An Interview with Brigadier
General Charles E. Sawyer

By JAMES ALNER, NEW YORK CITY

SHORTLY after his inauguration, President Warren G. Harding asked his personal physician, Dr. Charles E. Sawyer, to come to Washington and make a survey of the health and welfare activities of the Government with a view to their coordination. Dr. Sawyer was commissioned as a Brigadier General in the Medical Reserve Corps of the Army and given an office in the State, War, and Navy Building. Since he acts as spokesman for the President concerning matters pertaining to public health, THE NATION'S HEALTH takes this opportunity of presenting his views to its readers. Before giving them in detail, it might be worth while briefly to outline the events which have paved the way for the interest of the administration in public health.

The Historical Background

Many of our chief executives have believed with the great statesman, Disraeli, who is so often quoted as saying, that "public health is the foundation upon which reposes the happiness of the people and the strength of the Nation" and that the "care of the public health is the first duty of the statesman." President Arthur, for instance, asserted that "the health of the people is of supreme importance." Theodore Roosevelt, himself the personification of vigorous manliness, stated that "our national health is physically our

Charles E. Sawyer, Brigadier General, M.R.C., United States Army.

greatest asset." He also declared: "To prevent any possible deterioration of the American stock should be a national ambition." It was President Roosevelt who appointed the National Conservation Commission, to which Professor Irving Fisher made his notable report on "National Vitality" in 1908. During the presidency of Mr. Taft, strenuous attempts were made in 1910 to get a Federal Department of Health. The idea of such a department had been indorsed by the President in messages

to Congress, but the efforts were not successful. Few persons know that in 1917 a confidential advisor of President Wilson asked a number of health experts to prepare a program for a national health administration.

These early endeavors did not bear fruit, at least they did not result in the goal essayed—a national department of health. To the present administration, therefore, seems to have fallen the opportunity to advance the cause of public health in this country to a position never previously attained. The Republican platform itself pledged the party to the solution of social problems. It advocated a thorough system of physical education for all children up to the age of nineteen, including adequate health supervision and instruction as a remedy for conditions revealed by the draft. One plank referred to the public health facilities of the Government as follows: "The public health activities of the Federal Government are scattered through numerous departments and bureaus, resulting in inefficiency, duplication, and extravagance. We advocate a greater centralization of the Federal functions, and in addition urge the better coordination of the work of the federal, state, and local health agencies."

That the President had these matters in mind is shown by an excerpt from his first message to the Sixty-Seventh Congress:

In the realms of education, public

health, sanitation, conditions of workers in industry, child welfare, proper amusement and recreation, the elimination of social vice, and many other subjects the Government has already undertaken a considerable range of activities. I assume that the maternity bill, already strongly approved, will be enacted promptly, thus adding to our manifestation of human interest. But these undertakings have been scattered through many departments and bureaus without coordination and with much overlapping of functions which fritters energies and magnifies cost. Many subjects of the greatest importance are handled by bureaus within Government departments which logically have no apparent relation to them. Other subjects which might well have the earnest consideration of Federal authorities have been neglected or inadequately provided for. To bring these various activities together in a single department, where the whole field could be surveyed, and where their interrelationships could be properly appraised, would make for increased effectiveness, economy, and intelligence of direction. In creating such a department it should be made plain that there is no purpose to invade the field which the states have occupied.

The Preliminary Survey

It was in order to get authoritative information on the existing state of affairs that the President requested General Sawyer to make his survey. In doing this work, the General was fortunate in having much able assistance. The United States Bureau of Efficiency, for instance, the office of which is located only a short distance from that of the General, was able to supply much valuable data. Government bureaus, realizing that the result of the survey would accrue to their interest, cooperated from the first. Certain national voluntary agencies rendered much useful assistance, perhaps none any more than the National Health Council. This organization placed the facilities of its Washington office at the disposal of General Sawyer in gathering information and has been of considerable assistance along these lines.

General Sawyer occupies a large room in the northeastern corner of the State, War, and Navy Building. He is an intensely busy man. It seems as if everybody who has any kind of ideas on the subject of welfare feels the necessity of visiting the General and expressing them. To all, however, he listens attentively and politely. From many he has derived much benefit. In his anteroom one will see social workers, physicians, members of Congress, representatives of labor interests, educators, newspaper men, writers (he has been written up so much, he doesn't try to keep track of the articles himself), and

various other types of American citizens. He likes to describe himself as a country doctor. Before he came to Washington he conducted a sanatorium in Ohio, the management of which he has now turned over to his son. While he was not well known nationally, he was by no means a provincial figure. He has served as president of the American Institute of Homeopathy and is considered among the leading physicians in his home state.

When General Sawyer grants an interview, he is cordial, but does not hand out a cigar, as Mr. Coolidge used to do when Governor of Massachusetts. He has a formal sort of way of delivering a speech to the interviewer as sole listener. It is a kind of speaking-for-publication manner. General Sawyer is an interesting talker; there is no doubt of his sincerity.

The President, he declares, is whole-souled and generous. He has at heart the desire to increase the public welfare and he wants to make this country the strongest nation in the world, both physically and mentally. He regards public health as the Nation's greatest asset. He desires to have all our official welfare agencies brought together, so as to create the most efficiency. In this subject of public welfare we believe that there are three factors: education, public health, and social service. These three matters are being studied as the foundation upon which to build the superstructure of public welfare. If this survey proves that it is worth while, we shall have a new Federal department under which these affairs may be carried on.

Health Objectives Formulated

As a matter of fact, Senator Kenyon introduced a bill for a Department of Social Welfare in the Senate on April 12, 1921. On April 21 General Sawyer appeared before the Senate Committee on Education and Labor, to which this Bill had been referred, and outlined his plans for a department of welfare. As a consequence of his testimony, Senator Kenyon introduced in the Senate on May 5 a new Bill for a Department of Public Welfare. Representative Fess introduced a similar bill in the House on the same day. These bills were drafted after conferences with General Sawyer and embody his ideas.

The Fess-Kenyon Bill (S. 1607, H. R. 5837) proposes a new department under a cabinet officer. There would be four assistant secretaries, each at a salary of five thousand dollars a year. Each assistant secretary would be in charge of one of the following divisions: (1) Education, (2) public health, (3) social service, and (4)

veteran service. The Bill would abolish the following existing offices: Director, Bureau of War Risk Insurance; Surgeon General, Public Health Service; Commissioner of Education; Chief, Assistant Chief, and Private Secretary to the Chief, Children's Bureau; Federal Board for Vocational Education; and the Board of Managers, National Home for Disabled Volunteer Soldiers.

The following bureaus would be transferred to the new department: Children's Bureau (Labor); Bureau of War Risk Insurance (Treasury); Public Health Service (Treasury); Office of Education (Interior); Bureau of Pensions (Interior); Freedmen's Hospital; National Home for Disabled Volunteer Soldiers; United States Employee's Compensation Commission; Columbia Institution for the Deaf (Interior); Howard University (Interior); and St. Elizabeth's Hospital (Interior).

The Bill also provided that the President should have the power to transfer other bureaus at his discretion.

Hearings were held on this Bill on May 11, 12, 13, 18, and 20 before joint committees of the Senate and House. General Sawyer appeared as the first witness. He explained the features of the Bill and answered questions of the Committee. In conclusion he stated that he had no aspirations to direct the Department of Public Welfare and was working only for the best interests of the Country. His evident sincerity impressed the members of the Committee and one of them made a remark which for some reason does not appear in the printed report of the hearings. It was to the effect that General Sawyer could head the Department and that this particular committee member intended to vote to confirm him if he got the chance. This remark seemed to meet with general satisfaction. Senator Kenyon observed, however, that if the General declined, possibly some other citizen from Ohio might be prevailed upon to accept.

A Division of Interests

The principal objections to the Bill came from the educational group. They insisted that they could be satisfied with nothing but a cabinet officer at the head of an independent department of education. An entire day of the hearings was devoted to their arguments. Later, General Sawyer invited a number of these prominent educators and friends of education to his office and attempted to

convince them of the soundness and desirability of placing education under the Department of Welfare. The educators remained firm in their opposition, however.

Among the prominent health people who spoke on this bill were Surgeon General Cumming of the Public Health Service, who indorsed it with the exception of the clause abolishing the office of Surgeon General; Dr. William H. Welch of Johns Hopkins; and Dr. Edward Martin, state health commissioner of Pennsylvania. A number of speakers brought out the desirability of having a separate department of public health in the Federal Government, but they expressed the opinion that public health could well fit into this scheme of public welfare. The usual crowd of anti-medical freedom cranks opposed the measure.

At the time of writing this article (August 10) the Bill has not yet been reported from the Committees, nor has any action been taken upon it. General Sawyer states that the President is not yet ready to have the Bill acted upon. A Congressional committee on reorganization of the Federal Departments, known as the Smoot-Reavis Committee, is at present working on a scheme of reorganization. The Chairman of this Committee, who is also the representative of the President on it, has stated that he is to include in his recommendations a scheme for a department of welfare. He is working in close harmony with General Sawyer on this matter. It is probable that there will have to be some modification in the Bill. In August, Congress passed the Sweet Bill, which creates an independent Veteran's Bureau, directly responsible to the President. This measure provides for the consolidation of the Bureau of War Risk Insurance, that part of the Public Health Service dealing with the hospitalization, medical care and treatment of ex-service men, and the Federal Board for Vocational Education into one Bureau. Thus, the Veterans' Division in the welfare bill seems to have been taken care of in this Sweet Bill.

Another important health measure in which the President is greatly interested and wishes to see pass, is the Sheppard-Towner Bill for the Protection of Maternity and Infancy. This bill was introduced in the last session of Congress, the Sixty-Sixth, and passed the Senate and was favorably reported in the House. It was reintroduced in the present session and passed the Senate on July 22 by a vote of 63 to 7. The House has not

yet (August 10) acted upon it, but the Committee on Interstate and Foreign Commerce, to which the bill was referred, held hearings on it from July 12 to 23. One of the principal witnesses was General Sawyer, who appeared on invitation of Congressman Winslow, the chairman of the Committee. He told how the bill would fit into the scheme of the welfare department and indorsed its administration by the Children's Bureau.

Aid Local Enterprise

While the provisions of this Bill are well known to most health workers, a brief review may be in order. The bill provides for a method of cooperation between the Federal Government and the States for the protection of maternity and infancy. An appropriation of ten thousand dollars is made for each state which can qualify under the terms of the Act, and then a further appropriation is made, based on the proportion of population of the state to the total of the United States. This latter appropriation must be equaled by the state. The money is to be used for instruction in the hygiene of maternity and infancy by means of public health nurses, consultation centers, and other suitable methods. The administration of the act is vested in the United States Children's Bureau of the Department of Labor. The Chief of that Bureau is named as executive officer, with an advisory board consisting of the Surgeon General of the Public Health Service, the Commissioner of Education and the Secretary of Agriculture.

The President's solicitude for the public health is further shown by his action regarding the pellagra situation in the south. Relying on reports of the Public Health Service that one hundred thousand cases of pellagra were indicated in the cotton belt this year, on July 25 he wrote to the Surgeon General of the Public Health Service and to Dr. Livingston Farrand, head of the American Red Cross, asking that these two bodies cooperate in a survey of actual conditions with a view to making an attempt to remedy them. In his letter to Dr. Farrand the President wrote:

Recent reports of a distressing condition among the rural population in a large section of the Cotton Belt are confirmed by a public statement from the Public Health Service. They indicate that, due to the depressed cotton market, many thousands of people are unable to sell their one product for money wherewith to obtain a necessary variety of wholesome food, and that there is grave threat of an epidemic of pellagra.

It must bring a shock to the American people to realize that a great section of their own country, which they are wont to think of as immune from such experiences, is actually menaced with famine and plague. For that is what it would be called if it should befall in any other country, and we may as well give it its right name.

It is, of course, a consequence of the economic disorganization following the war, and it demands instant and vigorous attention. Our people, so long and so often moved by charitableness toward the unfortunates of other lands, will never permit such an affliction here at home.

The publication of these letters brought forth indignant denials from officials and members of Congress from the South that the conditions were as bad as painted. There seemed a general feeling that the President was sincere in his desires to be of service, but that he had overestimated the seriousness of the situation. The Surgeon General called a conference of thirteen state health officials, representing the southern states, at Washington on August 4. This Conference adopted resolutions to the effect that there is but little increase in pellagra over previous years. They recognized the necessity of coping with the problem at all times, however, and expressed their wishes for effective cooperation between state and Federal officials.

These examples show, as General Sawyer says, that the President considers the public health as one of the Nation's most valuable assets and that he wishes to do all in his power to assist this Country in making progress in its protection. The health of all the people is something in which everybody is and should be vitally interested. With such backing and support as can be given by the highest office in the country, there is no reason why the science of public health should not attain greater achievements than ever before in the history of these United States.

Birth Control Conference

A conference has been called in New York City for November 11, 12, and 13, which is the first American Birth Control Conference. Discussions are announced as follows: (1) The question of population and social aspect. (2) Medical aspect and private discussion of practical methods by authorized delegates. (3) Mass meeting and organization of an American Birth Control League.

The Conference will be attended by those economists, doctors, and social workers who consider that the time is opportune for a national discussion of controlled birth rate.

Mental Health Maintenance Emphasized

Mental Hygiene Takes Full Account of the Behavioristic Significance of Mental Attitudes

By R. R. SPENCER, M.D., P. A. SURGEON UNITED STATES PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

NO ONE for a moment would claim that there is a dearth of information in our literature upon the subject of health. Quite the contrary is the case; yet 90 per cent of it deals with physical rather than mental health. The study of the means by which mental health and efficiency might be attained is, of course, equally important and quite as interesting as physical health maintenance. It may be true that the attainment of complete mental health is a more difficult task to the average individual than that of physical health. It is evident, however, that its importance cannot be too strongly emphasized and it may be safely stated that the means to its attainment is available to all who take the trouble to seek it.

Health Is Defined

The term physical health is usually applied to the proper functioning of the body processes. As far as I know mental health has not been defined, so for our purpose, it may here be called that state of the mind in which the mental faculties and qualities so function as to be of the greatest good to the individual and the greatest service to the race.

While reviewing recently some of the fundamentals of modern applied psychology, considerable regret was felt that this information had not been received earlier in my preliminary education. Of the general course in psychology which had been received, all that can now be remembered is that it was a very uninteresting subject which taught something about the mind being the sum total of mental processes. Yet applied psychology is not only intensely interesting now but fills a long felt but heretofore indefinable need.

As a general rule, the average citizen considers psychology a difficult subject and gives it a wide berth whenever he meets it. Yet the fundamentals of this subject, when properly presented, are easily understood by anyone; and with its universal application in the schools, a better citizenship will undoubtedly follow. Not alone the teaching of the principles of psychology but the daily practice

Man has succeeded in reducing the forces within himself so as to build up a civilization; but, on the other hand, has gradually become so constituted that when these same forces are uncontrolled they destroy and distort his personality.

Hence the necessity of discovering in the heterogeneity of scientific studies the universal laws governing the processes of thought, the physiological basis of normal mental development, and the means of achieving dynamic control.

For it is not physical vigor nor mere incubus of knowledge that counts in improving the race, but the consistent stimulation of all factors which favor reactions on a higher plane.

and application of these principles is the real key to mental health.

Again, the habit of mental efficiency and health, properly implanted, will do much toward making clear the true relationship of mind and health and will eventually replace and neutralize some of the prevalent misconceptions upon this subject. For example, the influence of mind over matter, although a great truth, its limitations are not always realized, and when the limitations of any truth are not fully taken into account more harm than good may result.

The Interest in Health

When the statement is made that good health is the first and greatest of all assets; that with it everything is possible and without it practically nothing; that the maintenance of health is a duty we owe ourselves, our families, our business, our community, and our nation; that although the importance of health is obvious to all, yet few people give any thought or time to health until they are sick; one may justly be accused of dealing in platitudes and glittering generalities which form a part of every sanitarian's propaganda equipment. On the other hand, statements such as these do carry a great volume of

truth and are often times necessary in order to create a sufficient degree of feeling to stimulate people to act in behalf of their own welfare.

Fortunately, there never was a time when people in this country gave more thought to the preservation of health than now. This renewed interest in health may be partly explained as a reaction to the great human wastage caused by the late war. Ample evidence of this interest is seen in the phenomenal growth of the modern health conservation movement. The Red Cross societies, the anti-tuberculosis associations, infant hygiene, school hygiene, industrial hygiene, rural hygiene, community health centers and other welfare activities are all expressions of this great movement.

Mental Health Paramount

From another angle these activities, as pointed out by Sir Arthur News-holme, may be considered as manifestations of what Huxley has long ago called the ethical process—a process which is slowly replacing the jungle of law of “the survival of the fittest” by another, “the fitting of as many as possible to survive.” According to Huxley, this law “repudiates the gladiatorial theory of existence and in place of ruthless self-assertion demands self-restraint; in place of thrusting aside or treading down all competitors it requires that the individual shall not merely respect but shall help his fellows.”

However this may be, it is certain that one of the most important domains of all this broad field of health work is the maintenance of mental health, which may be classed as a subdivision of the larger and broader field of mental hygiene.

Since the success of all human undertaking is dependent upon the integrity of the mind, whatever may be said about the value of health conservation in general is doubly true in its application to mental health, for sanity of mind may justly be called the *sine qua non* of all success. For our immediate purpose, it may be pointed out that most health work very readily resolves itself into two distinct lines of endeavor: (1) the prevention

of disease, and (2) the maintenance of health. The first concerns itself with the study of disease with the idea of preventing it; the second with the study of health, with the idea of maintaining it.

In the field of mental hygiene, the maintenance of mental health begins where the prevention of mental disease leaves off. The prevention of mental disease usually leads to problems in eugenics and heredity, while the problem of mental health maintenance is largely a matter of environment and individual initiative, the latter after one has reached the age of accountability. Prior to this, the mental environment is beyond the control of the individual and rests mainly upon the influence of parents and teachers or upon the society in which one happens to be reared. Although this is a well recognized fact, it is rare to find, even today, a teacher or parent sufficiently equipped to furnish the child with the environment and training that the ideal of the mental hygienist demands.

This ideal should demand that each individual receive as early as possible and continue to receive throughout the formative period that environment which will insure the complete development of whatever mentality heredity has bestowed upon him. Of course, it is equally important to improve heredity, but that lies outside the sphere of individual health maintenance. Now, it is doubtful if any have ever received such an environment, and there are some who feel that this ideal, like the cessation of wars, may never be attained. But, of course, this is no reason why efforts should not be made in that direction.

The Field Is New

Indeed, some progress along this line is already being made. A noted example is the recent establishment of a psycho-educational clinic at the University of Minnesota. The stated purpose of this clinic is "to carry on intensive psychological measurements of individuals, the results of these measurements forming the basis for necessary educational adjustments. . . . On the basis of these data it is possible to reform bad and establish good habits." This clinic boasts that what it is doing on a small scale, American schools will do in years to come. Necessity for work of this kind is emphasized when we learn that conservative estimates from various sources agree in showing that there are thousands of mental defectives in New York state outside of institu-

tions, while the state itself is caring for about forty thousand. Undoubtedly, poor mental and social environment is as much a factor in the production of this large number of mental derelicts as poor heredity. If there are forty thousand mental defectives in New York, it would certainly be interesting, if it were possible, to estimate the number of normal individuals who are mental misfits or, in other words, whose environment has been so unfavorable as to retard rather than develop their natural abilities.

Yet in one respect man is fortunate in that mental maturity is, as a rule, seldom reached until long after physical maturity, and the period of mental vigor may last twenty, thirty, or forty years. In fact, some of the best work of genius has been done after sixty years of age. So those who have reached adult life and have missed good early mental influences, or have dissipated their mental energy, need not be discouraged; for all normal individuals are capable, in large measure, of deliberately choosing and controlling their mental environment. For example, it is possible to set one's self the task of seeking good companions or the association of good books, or correct bad habits, or regularly exercise certain of the mental faculties.

Everyone knows that a splendid physique can be attained by means of continued and regular exercise of the muscles; but few realize that the same law applies to the mind, and that mental poise may be attained by the proper exercise of the mental faculties.

And this brings us to the point where we can see the necessity for requiring first some knowledge of the elemental principles of how the mind works before we can really maintain mental health. Without such knowledge one is in very much the same position as the man who learns to run an automobile without knowing anything of the mechanism of the machine. When something goes wrong he is helpless, and outside assistance is needed before the machine is again working normally. Therefore, the maintenance of mental health hinges, for the most part, upon individual effort.

Train the Emotions

In order to further point out the importance of continued and sustained effort in this direction, if complete mental health maintenance is our goal, it might not be unprofitable to give briefly some idea as to the rôle

played by the emotional states.

Although a well known fact, few realize or profit by the influence of the emotional states upon our daily lives. Most people congratulate themselves that they are free beings, that the intellect decides and directs their actions, and that will is supreme over conduct. Yet after a little reflection it is seen that this is by no means the case. The major emotions of fear, grief, love, prejudice, and sentiments of various kinds exercise far greater control than the will or intellect in the lives of most people. As an example of what intellect fails to do and sentiment accomplishes without delay, it is only necessary to cite that familiar instance when you lie in bed long after the usual hour for arising. Cool reason, uncolored by emotion, tells you it is time to arise; but the idea is completely submerged by the snug comfort of the bed. Let the door bell ring and a friend be announced, you spring out of bed at once, the sentiment or fear of being found in bed at a late hour accomplishing what the intellect was powerless to do.

The power of the emotional states is not only shown in the conduct, but, what is sometimes just as important, this influence is so great that it may cause considerable bodily changes and influence physical health. This is particularly true if a given emotion is allowed to persist for a long period of time. Dr. W. B. Cannon of Harvard has demonstrated that strong excitement in man stops the secretion of the saliva, the gastric juice, the pancreatic juice, and the flow of the bile, as well as normal motions of the stomach and intestines.

The blood is suddenly shifted from the abdominal organs to the muscles and grain, the heart beat is accelerated, the coagulation time of the blood is lowered, the energy giving sugar content of the blood is greatly and suddenly increased and muscular fatigue is lessened.

All these changes are adaptive and purposeful reflexes preparing the body for violent energy, and show what a fundamental part the emotions play in our lives. The evil effects upon health are seen when one permits fears, worries, and anxieties continually to disturb the bodily functions. Cannon states that people who worry are evidently allowing the body to go on to what we may regard as a war footing when there is no war to be waged, no fighting or struggle to be engaged in.

While certain emotions, uncontrolled, cause bad effects and may en-

tirely upset mental and physical health, there are others, promoting both which are, in fact, essential. The emotions furnish the energy or fuel for our mental motors. It takes the heat of an emotion to weld an idea into vigorous effective action. All action is expressed with some degree of emotion, and its effectiveness is usually proportionate to the amount of feeling put into it. In the pulpit or on the stage it is usually the degree of feeling that one can put into the action that determines success. Anyone that has heard Billy Sunday, however much he may disagree with what the evangelist says, knows that every fiber of his being vibrates with feeling; so much so that thousands are persuaded to change their lives. The majority, however, fall back after a few weeks into the same life as before, because they are unable to summon or create sufficient feeling of their own to sustain them.

Emotion as Motive Power

No one is capable of long continued effort or hard work of any kind without a great amount of emotion or interest back of it. It is a common saying that the thing we do best is the thing that we are most interested in and will work at the longest. If the emotions or feelings are essential to hard work, they are worth cultivating and improving; for no one denies the value of hard, honest effort. Nearly all the lasting good things of this world are the products of hard labor. Work will often do more for mental and physical ills than rest; and many a physician prescribes the rest cure where it should be the work cure. This is why Uncle Sam has established a Federal Board for Vocational Education. Disabled soldiers are given work adapted to their particular handicaps, and when the man and job are properly adjusted, the curative effect is marked.

Study the lives of any one of our great men and you will find that every one has been a prodigious worker. But back of the characteristic capacity for work there has always been great feeling and emotion and zeal. It is stated that Darwin held the opinion, as the result of a lifetime of observation, that men differ less in capacity than in zeal and determination to utilize the powers which they have. Emerson said that nothing great was ever accomplished without enthusiasm. The fact that war stirs the depths of men's emotions and often brings out their best qualities has been frequently pointed out, but religion probably has cre-

ated many more good emotions than war and is not accompanied by war's great disadvantages.

Emotion is only one of the fundamental mental processes. The road, therefore, to mental health lies in the study and development of *all* of the mental faculties and virtues. The acquisition of knowledge is of course important; but, up to the present time, our educational system seems to have depended on it altogether. One of our foremost medical schools has for years required a degree in arts or its equivalent as an entrance requirement, but it may be noticed that this school, like others, supplies its full quota of failures. The value of such a high entrance standard is conceded, but it would be wise also to include proficiency in some of the mental virtues, such as honesty, good judgment, perseverance, power of concentration, imagination, and the like, as a part of this standard. Why have these qualities been overlooked? Is it not common observation that the worst possible crook is a scientific and educated one? Does not our school system unwittingly turn out some educated scoundrels here and there, because of our failure to take these essentials of mental well being into account?

These questions bring to mind a series of portrayals called "Life's Little Jokes," by one of our popular cartoonists, who has very well shown what our system of education does not do. He usually portrays two young men starting out in life together. One has a brilliant mind, leads his class and takes all the honors at college; the other is a dull witted individual who barely gets by. In later life the tables are turned, the slow wit is at the head of his profession, while the honor man at college is now obscured in mediocrity. Such cases not infrequently occur in reality, and the cartoonist's closing comment, "It's all wrong, it's all wrong," causes some persons to underestimate the value of a collegiate education. What is it that's wrong? Nine times out of ten the answer is that one developed his mental capacity by means of continued effort and hard knocks, whereas the other depended entirely on his natural ability and, because of it, was allowed to neglect the essentials of mental training.

No serious criticism of our schools is now justified because, fortunately, educators are beginning to see the need of developing mental qualities as the true basis of character and of placing less emphasis upon the mere

acquisition of knowledge, but the people as a whole are not aware of this need, and it is hoped that the future will see a great deal of progress in the field of mental health. Physicians will probably take the lead in this progress, because the most progressive element in the medical profession is already aware of its new responsibility and new relation to the community, as is shown by a paper read by Dr. Donald B. Armstrong of Massachusetts before the sociological section of the American Public Health Association, in September, 1920, in which he says:

"The theory of medicine has developed in three stages: (1) the physician existed as an individual in the community with the sole object of *making sick people well*. (2) There was added the conception that he might *also keep people well*—a social conception, requiring an organization, and hence our health departments and allied social devices. (3) Finally, there is being added a new idea, namely, that the physician should not only cure sickness and prevent sickness, but he should also create health."

In conclusion it may be stated that a very hopeful sign of the times is shown in the fact that one of our universities has very recently instituted mental tests as an entrance requirement, and another is establishing a psycho-educational clinic in connection with its medical dispensary.

Health Work and Motion Pictures

In his report on the years work of the National Tuberculosis Association ending June 1, 1921, Charles J. Hatfield, managing director, gives the following figures on the motion picture service of the Organization:

During the year 450 bookings were made and fifty-nine films sold. At the present time nineteen films of ten different subjects are available for loans. As a result of the general demand the Association has just produced a new motion picture dealing with the Modern Health Crusade. Arrangements have been made for the production of another picture dealing with the hopeful or cure side of tuberculosis which will be released about November 1. The films have been a highly effective adjunct.

Science should always protest against the practice of making children work before the fifteenth year, for this causes a misshapen, crippled, and stunted humanity. Where are the legislators who have sufficient courage to check this social evil?—Amar.

Standardized First Aid in Industrial Plants

Forethought and Training Insure Intelligent Reactions in Emergent Situations

BY R. A. BRINTNALL, M.D., DIRECTOR OF FIRST AID, LAKE DIVISION, AMERICAN RED CROSS, CLEVELAND, O.

IN PAST years the large corporations which have been doing the splendid things along lines of welfare work for their employees seemed to think that any publicity of activities would be misconstrued by the public in general. That time is past, and today the public not only desires to know of such service but is delighted that such service is being given and sees in it a mighty help toward Americanization and mental, moral, and social uplift. This is as it should be, and the coming years will see in larger measure unremitting effort to serve humanity everywhere and at all times, in a proportion commensurate with humanity's needs.

The instruction of employees in first aid is a service of this kind, but the service is not confined to industry alone. The demand is a logical result of the hazard of traffic conditions in our cities, the more common use of automobiles and power machines in the country, and the growing complexities of industrial life. When we stop to consider the large number of accidents each year, with the resultant death rate that is estimated at seventy thousand—71,364 violent deaths in 1918, exclusive of suicides—along with the fact that accident is no respecter of person or place, it would indicate that the larger the number of people trained in what to do and what not to do in an emergency, the greater the asset to any community.

A General Requisite

There is so much that a person can learn to do at a time of accident or disaster that it is almost a requirement of good citizenship to have this knowledge. Because of the frequent occurrence of accidents, and because many of them take place under circumstances which make it impossible to get a physician at once, the value of training in first aid cannot be overestimated. This has been recognized by one of our large industrial companies, which for eight years has been giving this instruction to its employees on company time and at company expense. This article constitutes a story of how they have carried on this work and gives a de-

Just as the success of an individual requires unity of interest and complete integration, so does effectual group reaction depend upon the formulation of group objectives and training in team work.

Men are better individuals for this extension of interests and coordination of effort. Thus specialized efforts looking toward the control of specific industrial problems have served to illuminate innumerable social and therapeutic questions.

scription of one of the largest first aid contests ever held in this country.

The Bell Telephone System has the unique distinction of bringing to the public a practical demonstration of this kind of work. Since the winter of 1912-1913, the Bell Telephone Company of Pennsylvania has been training its men in first aid work and life saving. The training has been given to the employees by forming units in each town and in each line of telephone work so that there is available at all times one or two men in each department able to render first aid to the injured. In this manner much has been accomplished in the way of concrete results, one significant indication being the reduction in the number of lost-time accidents as shown by the following comparisons:

Lost time per every 100 employees was—in 1916, 10.47; in 1917, 7.62; in 1918, 5.66; in 1919, 3.98; in 1920, 2.69,—which means that they have

succeeded in reducing the lost-time accidents in 1920, 7.78 as compared with 1916.

As the training of these groups had been carried on for a number of years, it was conceived that active competitive effort between groups would help to maintain a continued and well sustained safety activity. To this end there were organized safety meets in which the groups of the different divisions competed with each other for a record. These have been carried on by the Bell Telephone Company since 1916, and a description of the last meet at Philadelphia will give a very good idea of how these contests were carried on.

During the early part of this year the Bell Telephone Company of Pennsylvania had three first aid contests, one at Pittsburgh, one at Harrisburg, and the third and last at Philadelphia. This contest was held under the auspices of the Philadelphia Division of the Bell Telephone Company and the American Red Cross. There were eleven teams of five men each entered in the contest. The rules governing were as follows:

In the performance of each event the captain of the team designated the members or members to perform each event after it had been announced.

The captain controlled his team in its work, but only when the full team was engaged. The captain or other members could not prompt the person or persons performing in the event unless they were actually participating.

The captain could himself contest in one and two-man events.

The Harrisburg Division in the First Aid Contest of May 9, 1921.

The Philadelphia meet, showing guests on platform and prizes to be awarded.

An event embraced a problem which called for treatment of one or more injuries and the handling of the patient. In the Philadelphia event there were five problems:

Problems for Demonstration

Problem No. 1: Full time event.—Patient found with left ear torn off, right collar bone broken, cut two inches long on calf of left leg, expelling blood in spurts; simple fracture of right leg below the knee.

Give first aid treatment and prepare for transportation. Time allowance, eight minutes.

Problem No. 2: One and two man events.—(a) One man event (patient to sit on a chair). Simple fracture of the seventh and eighth ribs on right side. Cut on top of head. Profuse bleeding. First aid treatment. Regular patient of the team to administer the treatment to the captain.

(b) Two man event. Left foot crushed and right hand cut off at wrist. Use closed hand as stump. First aid treatment and carry patient—(two-man carry) from a sitting position on the floor around one end of the enclosure. Time allowance, four minutes for both events, not including the time consumed in carrying patient.

Problem No. 3: Full time event.—Patient found unconscious in smoke-filled room. Drag patient four feet to a place where an upright position can be obtained, then carry across back to where three men are located. All four men resuscitate victim by means of artificial respiration for one minute—prone pressure method—and treat burns on back of neck and left upper arm of shoulder. Carry patient around one-half of the enclosure on improvised stretcher made of poles and coats, or poles and blanket.

Problem No. 4: Full time event.—A man met with an automobile accident in which he received the follow-

ing injuries: Compound fracture of the right thigh (middle third); lower jaw fracture, with slight laceration on upper right side; dislocated left shoulder. Give first aid treatment and prepare for transportation. Time allowance, eight minutes.

Problem No. 5: Full time event.—Patient found unconscious lying on an electric light wire. Remove, resuscitate, and treat burn on left shoulder blade and an injury to right eye. Carry patient on stretcher around the enclosure, over the obstacle, and through the narrow passage, in arms.

The teams had no knowledge of the problems in advance of the contest. Just before the performance of each event the chief judge announced the problem and the captain of each team was at the same time given a written copy of the problem and allowed two minutes in which to discuss it with his team before starting work.

Each team had a standard bearing the name of the team. At the conclusion of the event the captain held the standard aloft until recognized by the timekeeper, thus signifying completion of the problem. The team remained at its post until relieved by the judge.

Red Cross Standards

The Industrial Edition of the American Red Cross "Textbook on First Aid" applied in this contest. Each team participating had been trained in first aid according to Red Cross standards. The awards given were: First—Division Trophy and Red Cross Medals to the team having the highest score. Second—American Red Cross Certificates to the team with the second highest score. Third—Cup to district having the highest

percentage of employees participating in the preliminary contests.

The judges were all physicians and performed their work progressively. Judge No. 1 judged Team No. 1 in Event No. 1, and he judged Team No. 2 in Event No. 2, etc. Judges thus progressed in each event to the team of next higher numerical designation, returning to the first team when they had progressed through all others.

Each judge was required to scrutinize the work done in each event and could call on the captain or member of the team who applied the aid, to explain his treatment.

Suitable record sheets for use of the judges were furnished by the chief judge prior to each event. These were used for recording the discounts and were delivered to the chief judge after each event, who, in turn, handed them to the tellers to be recorded.

Special Events Arranged

Ties were decided by a special event to determine the relative standing. All events began and stopped at the sounding of a bell. Signals were as follows:

(1) One ring called for attention of captains for instructions from chief judge.

(2) Two rings indicated, "Begin work" and not to start before the signal was given.

(3) Three rings indicated time allowance for completion of problem was ended.

Time was not an element unless the team of men performing the problem exceeded the allotted time or failed

to give treatment promptly. A penalty of one point for each minute, or fraction of a minute, was given for time in excess of the allowance.

The Fifth Annual First Aid Contest held under the auspices of the Philadelphia Division of the Bell Telephone Company and the American Red Cross at the Third Regiment Armory on Wednesday, May 18, was from all angles the most complete and successful ever held by that division. The new records which had been established at each of the four previous annual contests were at the last meet pushed up very close to the top.

It was a veritable three-ring, two-fisted, one-hundred-proof exhibition of what men can do to prevent injury and save lives. Safety devices and safety exhibits were placed all around the room, together with data describing what had been accomplished and what could be accomplished. One thing of interest in the exhibits was the fact that employees of the Bell Telephone Company, through their knowledge of first aid, have saved the lives of nine persons not in the employ of the Bell Telephone Company, this by happening along at the time of the accident. Several of these instances will be given in detail in the latter part of this article.

More than two thousand eight hundred spectators were present in the big event. The doors were open at seven o'clock to allow those arriving early an opportunity of looking over the exhibits. Many of the teams and their rooters met at appointed places and marched into the Armory waving flags and banners, wearing colored caps and badges, and accompanied, in some instances, by groups of their men dressed in historic and comic costumes. One outfit had a comic Kazoo band, with a goat for a mascot. The plant men of the different divisions and districts who came out to root for their teams took their seats in the spaces allotted them and sang their songs and yelled their cheers under the leadership of their own cheer leaders. A large number of guests, many of whom came from different parts of the country to witness the event, were seated on the platform at the front of the Armory. Among these were Mayor Moore of Philadelphia and representatives of the Bell Telephone Companies in the United States and Canada.

There, too, at the opposite end of the hall, were the Building Team, which won the cup at the Pittsburgh Division Contest, and the Cumberland valley Team, which carried off the

Safety museums throughout the country and objective demonstrations everywhere of what constitutes safety both in practice and equipment, carry home their life saving lessons.

Harrisburg Division trophy, as well as a team from Newark, N. J., which was the title winner in the New York Telephone Company's First Aid Contest.

At the proper time these three teams marched around the rectangle to their seats, to the martial music of the Third Regiment Band, which was on hand for the occasion. Next came the cup, mounted on its pedestal and bedecked with flowers and ribbons, borne by four office boys in uniform. At last came the competing teams from the Philadelphia Division—eleven in all—which were greeted on all sides by the acclamation of their fellow workers in the rôle of rooters.

The Results Summarized

Mr. H. B. Porter presided at the meeting and in his introductory remarks briefly called attention to some of the things accomplished in accident prevention and first aid:

During 1920 the Division forged ahead, scoring the best records for reduction of accidents in its history. The Accident Prevention Competition was very close. Under the rules the forces are rated in accordance with the reduction in disability days per one hundred employees, compared with their own record for the three years preceding. Four of the forces came through the year with 100 per cent records, having no lost time for accidents. One group had no disability accidents from September, 1918, to the end of 1920, a period of twenty-seven months, with an average of 130 men, or 87,750 working days. The combined record of the four groups with no lost time from accidents up to the end of 1920, approximates a total of 173,550 working

days, the comparative record for the Philadelphia Division being as follows:

	1916	1917	1918	1919	1920
Number of lost time accidents per 100 employees	12	8	7	4	1.4
Days lost from accident per 100 employees	115	98	75	45	21

Progress in First Aid team work may be judged by the following figures, the second column showing the number of five-man teams in preliminary contests and the third the percentage of entire force eligible represented on teams:

Season of—	Preliminaries	Percentage in Finals
1916-1917	163	40
1917-1918	222	63
1918-1919	246	78
1919-1920	347	93
1920-1921	308	98

As the teams performed their work many hundreds of eyes watched their every move. A considerable number of spectators had themselves taken part in the first aid team work in preliminary contests and doubly appreciated the efforts of their representatives. During working periods the crowd became quiet and tense, only to break forth in cheers as their participating team would raise its banner, denoting the completion of a problem.

After the fifth problem was completed and the tallies were counted by the tellers, Mr. Porter read the scores to the eager groups of contestants and spectators as well, the Camden team taking off the honors. The scores were as follows:

Camden	99.4	Chester	95.4
Equipment	99.0	Motor Vehicles	95.4
Morristown	98.4	Trenton	94.8
Maintenance	98.0	Wilmington	94.4
Buildings	97.0	Construction	92.6
Atlantic	97.0		

Major Shields, on behalf of the American Red Cross, presented medals to the members of the winning team,

If first aid in industry is to become standardized, rules and regulations must be put to repeated demonstration. It is quick reaction time, individually and collectively, in emergencies, that makes such work effectual.

and the Red Cross Certificates to the members of the second team.

Team Work Adds Value

The snap and technic of perfect first aid team work demonstrated beyond a doubt what first aid training can do in the promotion of health and the saving of life in industry.

Early in their safety efforts the Bell Telephone Company realized that effective first aid training can only be acquired by actual practice. In the treatment of minor injuries such as cuts, abrasions, or burns, it is important to know what materials should be used and how to apply them effectively. To place a bandage so it will serve its purpose and remain secure, or properly to put on splints for a fracture, it is necessary to work on some actual problem. To cope with serious cuts or arterial bleeding, some knowledge of the location of the arteries and the pressure points is required, and to restore life when breathing has been suspended, the correct application of artificial respiration must be known.

It would seem that the Bell Telephone Company has demonstrated beyond any doubt the value of first aid training among employees. The different opinions on the subject held by various industrial physicians is due mostly to the fact that they have never attempted to find out just what first aid among employees means. Instructing employees in first aid makes no attempt to make physicians out of them. On the contrary, they are always instructed to call a physician; but a physician, like a policeman, is usually not around when you want him, and the knowledge of first aid and a knowledge what *not* to do, as well as what to do, is very essential.

The Red Cross wishes to carry the message of first aid wherever it can and is willing at all times to do anything in its power to assist any industry or group of persons to this end. This organization has endeavored to promote classes in first aid throughout the entire United States. These classes are taught by a practicing physician of good standing, using the American Red Cross "First Aid Textbook" and giving the course under standards set up by that organization. The course comprises fifteen lectures and demonstrations of one hour each, or ten lectures of one and one-half hours each, a certificate being given each student upon the completion of his course. In order to secure American Red Cross First Aid instruction, application should be made directly to the local Red Cross Chapter of the city or county in which one resides. In the absence of a chapter, application may be made to the Director of First Aid in the Division in which one happens to live. A list of the American Red Cross Divisions with the states included in each Division, and the address of the central office is given herewith:

Northwestern Division.—Alaska, Washington, Oregon, and Idaho. 315 University St., Seattle, Wash.

Pacific Division.—California, Nevada, Utah, and Arizona. Civic Center, Hyde and McAllister Sts., San Francisco, Calif.

Central Division.—Montana, Wyoming, North Dakota, South Dakota, Nebraska, Minnesota, Wisconsin, Illinois, and Iowa. 308 North Michigan Ave., Chicago, Ill.

Southwestern Division.—Colorado, New Mexico, Kansas, Oklahoma, Missouri, Arkansas, and Texas. 901 Equitable Bldg., St. Louis, Mo.

Lake Division.—Michigan, Indiana, Kentucky, West Virginia, and Ohio. Plymouth Bldg., Twenty-second and Prospect, Cleveland, O.

Southern Division.—Louisiana, Mississippi, Alabama, Georgia, Tennessee, South Carolina, North Carolina, Virginia, and Florida. 249 Ivy St., Atlanta, Ga.

Atlantic Division.—New York, Pennsylvania, Connecticut, New Jersey, Maryland, and Delaware. 44 East Twenty-third St., New York City.

New England Division.—Rhode Island, Massachusetts, New Hampshire, Vermont and Maine. 73 Newbury St., Boston, Mass.

As to the value of first aid, not only in industry but in all walks of life, the following examples of what has been accomplished should be convincing proof:

Last January, while three of the Bell Telephone Company employees were working along Wilmington Haymorton State Highway, they were appealed to by a man who stated that a big truck had crashed into a pole about a quarter of a mile away, at the foot of a steep grade. The men appealed to, having been trained in first aid by the Bell Telephone Company, went immediately to the scene of the accident in the company's car, where they found the driver of the truck so tightly jammed in the wreckage that it was a difficult thing to remove him. After his removal it was found that the steel plate on the dashboard had almost severed the left foot above the ankle and he had been badly cut and bruised about the head and face. As soon as the man was moved the leg started to bleed profusely, with all signs of arterial bleeding. Their knowledge and ability to apply a tourniquet probably saved the man's life. The man who accompanied the driver had a compound fracture of the right arm, which was dangling at his side and paining him very much. The first aid knowledge of the relief workers enabled them to put this arm in a splint, in a comfortable position, until the patient could reach medical aid.

On March 19, two employees of the Bell Telephone Company at Shooters Island, near Mariners Harbor, heard a cry from the men on a gasoline launch that was bringing employees to the shipyard. The exhaust from the gas engine had escaped from the muffler into the cabin of the launch, overcoming several men, who were in varying degrees of prostration. On reaching the launch they saw a negro worker stagger to the deck gasping for breath and reel overboard. Other dazed men were making their way to shore. In the excitement of fishing the negro from the water, the cabin was not investigated for a few minutes. Later they discovered the body of a young man lying unconscious on

the cabin floor. Breathing had ceased by the time the man was taken on shore. The Telephone Company men, who had been trained in first aid, immediately started artificial respira-

tion by the prone pressure method and, after about ten minutes of vigorous work, breathing was resumed and the patient out of danger. These men had been given the opportunity to put

to practical test what they had learned in first aid classes, and in this test they demonstrated their ability to save life. Such knowledge and training should be universal.

Illumination as a Factor Favoring Production

Lighting Codes Need to Consider, Along with the Nature of the Lighting, the Reactions of the Worker

BY R. E. HARRINGTON, LIGHTING SERVICE DEPARTMENT, EDISON LAMP WORKS, HARRISON, N. J.

THE question of correct and adequate artificial illumination is one which warrants careful consideration by plant managers. It is one form of expenditure which brings the greatest returns for the money invested. In spite of this fact, many plant managers have neglected this opportunity to increase the overall efficiency of their plants. This is evidenced by the many examples of factories that are not only inadequately illuminated with regard to the amount of light, but are improperly lighted from the standpoint of reflecting equipment and location of lamps.

A plant manager, in planning for operation must include, in his general scheme, a means of providing artificial illumination. This, of course, means an initial investment in material and work for the installation of the system. That it is a sound investment to plan a system that will give proper, as well as adequate, illumination will be shown later on. In plants already equipped, but poorly lighted, it will be found economical to discard the old system and install a modern one.

With a properly designed and installed lighting system there will result, as contrasted with the conditions under a poor system, better health conditions, less labor turnover, greater activities, better workmanship, fewer accidents and decreased spoilage. All of these factors combined assist toward the desired end—increased production.

Health of the Worker

No one needs to emphasize the absolute necessity of protecting the eyesight of the worker. If sufficient illumination is not provided, the eyes are continually subjected to a strain in their attempt to discern detail. This rapidly fatigues, lowers the bodily efficiency and may produce permanent injury. Even with plenty of light, if brilliant light sources are

permitted to be in the field of view, bad health conditions result.

Several states, recognizing the beneficial effects of illumination on the health and safety of employees, have adopted lighting codes. These stipulate the minimum intensities permissible for certain operations, and also indicate the desirable intensities. These codes also indicate the allowable equipment to be used in order to eliminate glare, etc.

Good lighting is also reflected in the faces of the operators, in the form of healthful, buoyant spirits. Bad lighting is irritating because it makes it difficult to see, and strain is involved in the efforts of workers to adapt themselves to unnatural conditions. The mind, unconsciously, perhaps, becomes obsessed with the idea that it is being imposed upon. Everyone has seen this condition evi-

dent in employees; possibly the reader himself has experienced this feeling of resentment. Bad lighting will react to produce nervous, irritable, discontented employees.

Any plant manager knows that the experienced or trained man is an asset not easily replaced. If this man has been working continuously under insufficient illumination, its detrimental effect will eventually show up in his failing eyesight. He becomes incapacitated at the very time when he should be yielding the biggest return on the investment made in training.

The general appearance of the plant is materially improved, on account of the cleanliness which of necessity results. Dirt and refuse will not be permitted to lodge everywhere, if it is revealed to the scrutinizing eye of the superintendent.

The illumination in this card room in a southern cotton mill is accomplished by means of 300 watt lamps in deep bowl enameled steel reflectors. The white walls and ceilings, as well as light colored materials, assist in making this a very cheerful work room. Every part of the space is well illuminated, moving parts are easily seen, and work can be carried on with maximum speed.

An excellent example of high intensity illumination. The lamps are 200 watt, placed near the ceiling, with reflectors. An intensity of over ten-foot candles is provided. Employees in such conditions as this will be contented. Even though the work carried on in this case (cutting material for flags) is likely to produce a considerable amount of scrap, cleanliness is a direct result of high intensity illumination.

Dark corners always tend to gather waste material.

The question of shop sanitation is one that is receiving ever increasing attention, for an employer fully realizes that a healthy operator is an asset to his plant. Proper illumination is one of the greatest helps in attaining this result.

Labor Turnover Affected

It has been demonstrated with absolute certainty that everyone prefers a cheerful, clean, well-lighted room as a place to work. If a shop is well lighted, it will perforce be clean and will become a veritable magnet in attracting help. Cases are on record, where one mill in a section has been markedly better illuminated and has actually, through this means, obtained the very pick of the hands in the surrounding country.

At one time, not so far distant, it was assumed by many employers that a continual changing of employees was the best means of keeping down labor cost. Today this is not true, as such a method disrupts the organization, increases mistakes and accidents and, in fact, lowers the entire efficiency of the plant.

This, then, is the changed viewpoint of the employer as regards labor turnover. Parallel with this change has been one of as great importance in the case of the employees. They have been gradually taking a more

active part in saying what their working conditions shall be. If these are not satisfactory, they will quit and go where conditions suit them.

Since adequate illumination has a very marked influence on many of the items which labor is vitally interested in, such as health, safety, etc., it is obvious to conclude that the well-

lighted shop is one in which the labor turnover will be at a minimum, other things being equal.

A survey of the accident records of insurance companies show that the greatest number of accidents occur during the days of least natural light. These records also show that about 25 per cent of all the industrial accidents might have been avoided, if adequate illumination had been provided. In fact, insufficient illumination is frequently held by juries to be contributory negligence. These points are, in themselves, sufficient evidence of the relations between correct illumination and safety. For further material on the relation between illumination and safety, refer to Lighting Data, Index 18.

Spoilage a Result

There is no doubt that spoilage and "seconds" are one of the greatest "bugbears" of the manufacturer. Spoilage means a direct loss, as there is no return on the investment in material, labor and overhead. "Seconds" are nearly as bad; for, while they have some redemption value, they represent as much investment as "firsts," but not as much selling value.

That correct and adequate illumination has a very marked effect on the question of spoilage, is recognized. The mechanic can more easily and accurately read his blueprints, micrometers and gauges. When working to thousandths of an inch, the reading of a micrometer a thousandth

A treering room in a shoe factory with lighting so chosen and so placed that all working points are well illuminated. Such lighting assures a high quality of product, as every operation can be carefully observed.

off, may mean the difference between a "first" and a "second."

This argument does not alone apply to the mechanic. The carpenter, the weaver, in fact, everybody will find it easier to work correctly under a good system of high intensity, than under many of the systems at present in use.

One of the aims of the plant superintendent is to keep down spoilage. Since correct illumination is one of the obvious means to this end, it is surprising that so little attention is paid to it.

Lighting and Production

All of the effects of adequate illumination just considered have a very marked influence on production. It is obvious that a sanitary plant in which the employees are contented, and where accidents and spoilage are at a minimum, must be one in which production is high. There are other reasons, also, why the well lighted plant shows better production than the poorly lighted one.

It is axiomatic that, for a plant to operate at all, it is necessary to provide means of illumination. Natural lighting in modern plants is obtained by the use of large window areas, and care is taken in designing these windows, in order to secure the best natural lighting conditions. Why should not as much care be taken regarding the artificial lighting? The latter must be paid for, while the former is free.

High level, well diffused illumination is essential where fine work and polished surfaces are encountered. In this machine shop approximately nine foot-candles are secured through the use of 300 watt lamps in reflecto-cap diffusers.

What are some of the effects when the artificial lighting is inadequate? The employee has been accustomed to daylight intensities, and if, when the artificial system is turned on, the intensity is low in comparison, his movements must slow up. He must be more cautious, for he has not the confidence which comes with clear vision. If he cannot readily see the figures on his micrometer or gauge, he loses time checking his work.

If he drops a tool, or piece of work, and it falls into a dense shadow, a few moments must be spent in searching for it. If his artificial light is of a type which is under his control, considerable time may be spent in adjusting it to suit his whim. It is perfectly obvious that all these items combine to decrease production. Conversely, if the illumination is adequate, the workman proceeds at his normal speed, and one can scarcely notice the effect of the diminution of daylight.

In addition to these effects, it is known that, under high intensity illumination, the eye functions more rapidly and more accurately than under low intensities, which means that the employees are able to perceive details more easily and correctly. This effect can be interestingly shown by means of a shutter arrangement similar to that found in cameras. A printed letter or figure should be placed back of, and close to, the shutter opening. When the shutter is operated under low intensity illumination it is impossible to distinguish details of the letter. If high intensity illumination be substituted for the low, it will be found that the letter can be read with perfect ease.

It has been stated that the above mentioned points are theoretical, and that the cost of installing and operating a good system outweighs the saving of employees' time. That this is not true, is shown by the following table of annual costs. This table is based on the use of a 100 watt Mazda

Night view of an office with high level general lighting. The semi-indirect unit is employed. When such a system as this is correctly designed and installed, there is no necessity for locating desks with reference to the lighting units in order to secure satisfactory illumination, and work after sunset is as satisfactory as during the daytime.

C lamp per operator per 100 square feet, and shows the very small saving in time required to offset the cost of operation. In the tabulation it is assumed that the lamp burns two hours per day, three hundred days per year.

Cost of lamp (list, subject to discount)...\$1.10
Cost of enameled steel reflector (list, subject to discount)..... 2.50
Estimated cost of wiring, per outlet..... 6.00

Total first cost.....\$9.60
Interest on investment at 6 per cent.... 0.58
Depreciation on reflector and wiring at 12½ per cent..... 1.06
Power at 5 cents per kw-hr..... 3.00
Cleaning at 3 cents per cleaning, two per month72

Renewal of lamp $\frac{600}{1000} \times \1.1066

Total\$6.02
Wages for 8 hours per day, 300 days, at 70 cents per hour are \$1,680.

Ratio of cost of lighting per man to wages \$6.02

$\frac{6.02}{1680} = 0.356$ of one per cent.

These figures, which are based on assumed conditions less favorable than ordinarily found, show that if a workman saves three minutes time per day, due to correct lighting, the entire operating cost of the system is paid for. They do not take into account the much smaller differential between the cost of good and poor illumination. Surely any employee will lose much more time than this under an inadequate system of illumination, when it is necessary to go to an individual lighting unit to read his figures, or to adjust the lamp in order to see his work better.

On the basis of the total cost of production, this percentage becomes so small as to be almost negligible. Indeed, it is surprising that the one factor having the greatest effect on production at minimum expense has, until recently, been neglected by the industrial world.

The arguments, so far advanced, have as their basis what has been considered, up to the present time, as adequate illumination for industrial plants. It is of interest to note, however, that what is considered at present as adequate illumination, is of much higher intensity than that deemed sufficient several years ago. This is due to several factors, such as the introduction of incandescent lamps of much higher efficiency, the higher cost of labor and materials, the demands of workmen for better illumination, the realization by employers of the beneficial effects of increased illumination, etc.

Too High Intensities

What, then, are the limiting foot-candle values for artificial illumination, and is there such a thing as too high intensities? There are no limiting foot-candle values for artificial illumination with regard to the abil-

ity to see, provided the lighting system is properly designed and so installed as to avoid glare, etc. That the eye is able to adapt itself to very high intensities is evidenced by the perfect ease with which an employee is able to work near a window during a sunshiny day. The intensity in this case might easily range from 500 to 1,000 foot-candles. The question is properly not how much light, but whether proper use is made of a given light.

With regard to practical operating conditions, the amount of light to be used is influenced by economic conditions. That is, there is a point at which the cost of supplying higher intensities overweighs the results from increased production. What this point is, however, has not been determined. That we are far from it, on the basis of present day intensities, is evidenced by production tests made under increased illumination. That this relation of the amount of light, to the amount of production is of the greatest importance is shown by the attitude of many plant managers. In actual tests increased production under higher intensity illumination ranged from 8 per cent to 27 per cent, this over a period of a month under low intensity and a month under high. Parallel with this increased production, the high intensity illumination was found to result in better health conditions, less labor turnover, fewer accidents and spoilage.

Foot-Candle Meter

In order for the plant manager to determine the intensities throughout his plant, it is desirable to have available an instrument, by means of which this may be done easily and quickly. The foot-candle meter is an instrument self-contained and portable which meets these requirements. Because of its small size, (7½ in. by 6 in. by 1½ in.), it may easily be used to make illumination readings at any desired point. The instrument is calibrated before being shipped and, by means of the rheostat and voltmeter, which are a part of the instrument, it is possible to read intensities varying from 0.1 to 40 foot-candles. Although it is not quite as accurate as a laboratory instrument, it is sufficiently accurate to be of real practical value. At least one foot-candle meter should be a part of the equipment of every industrial plant.

By means of this instrument, a check may be kept on the lighting conditions in the plant. The manager or superintendent may easily

determine whether or not the illumination for any given operation is comparable with what is considered sufficient for that operation. Complaints of various workmen regarding inequalities in illumination are readily settled, for the foot-candle meter will show the results secured.

Technical training is not necessary to the successful operation of the instrument. With a little experience, anyone may read the resulting illumination. All that is necessary is to operate the rheostat until the pointer on the voltmeter comes to the indicated position. The foot-candle meter is then placed at the desired location and the illumination read by balancing the light and dark spots on the face of the instrument.

Congress Considers Many Public Health Matters

One hundred and twenty-one of the more than eleven thousand bills and resolutions that have been introduced in Congress since it convened in special session last April and up to the time when it recessed on August 24, have been concerned with public health or closely allied matters. This information comes from the National Health Council, the Washington office of which has issued eleven bi-weekly reports on national legislation of interest to health workers, during the first session of the Sixty-Seventh Congress. Of the 121 bills listed, eighty have been abstracted and their progress followed carefully. The other forty-one were considered of only indirect importance and so were merely cited. Statement No. 11 of the reports contained a review and index of all this national health legislation. Although these legislative reports were originally intended only for the members of the Council, the demand for them has been so great from other organizations that arrangements have been made to supply them at cost price, twenty cents an issue. They are prepared and distributed by Mr. James A. Tobey, Washington representative of the National Health Council, 411 Eighteenth Street, N. W., Washington, D. C.

Pennsylvania Health Laws

The Pennsylvania Department of Health has just issued a bulletin giving a synopsis of the health laws of that state covering advertisements, the use of trucks, the disposition of dead bodies, food regulations, garbage, housing, as well as contagious diseases and numerous other regulations.

Medical Measures Against Venereal Diseases*

The Necessary Clinics, Diagnostic Facilities and Cooperative Plan Between Physicians and Clinics

By COLONEL L. W. HARRISON, MINISTER OF HEALTH, WHITEHALL, LONDON.

IT IS generally agreed that the justification for the provision at public expense of venereal disease clinics is the necessity of preventing the spread of disease by rendering the largest possible proportion of the infected population non-infective. Public centers are necessary because a very large section of the infected population would, but for the public centers, resort to unqualified persons for treatment, or, if they sought the advice of experts, would be unable, for financial reasons, to continue treatment until definitely non-infective.

A Three-fold Problem

The arrangement and conduct of public venereal clinics must have regard to three main factors, two of which militate strongly against their success as a public health measure, and the third is important to the public purse. The first is the fear of disclosure which is felt by most patients. The second is the tendency of most patients to cease attendance as soon as discomfort or disfigurement have ceased, which is long before they have been rendered non-infective. The third factor is the very large numbers of patients to be dealt with, so that the universal provision of centers is inevitably very expensive and, consistently with the maximum of efficiency, the arrangements must be planned with very strict regard to economy. To meet the fear of disclosure in Great Britain centers have as far as possible been established at general hospitals, so that the purpose of the patient's visit may be hidden. It has been found, however, that, where it has been impracticable to establish a center at a general hospital in a large town or city, the center has been well attended. In fact in 1919 the two largest records of attendances were at "ad hoc" centers, viz., the London Lock Hospital and the Nottingham Center. As further concessions to secrecy, patients' names are registered confidentially and thereafter they are known by numbers. To maintain attendances, reliance is placed on public propaganda and the

personal influence of the medical officers. Other measures directed to the same end are examination in decent privacy, arrangements to avoid undue waiting, and arrangements generally to meet the patients' convenience.

With regard to economy, the most important measure is the provision of premises which are convenient to the purpose. The temptation is to economize on first cost, and to provide premises which cause the staff unnecessary labor. In any clinic with a constantly increasing number of patients a time must come sooner or later when either the staff must be increased or efficiency will suffer. Obviously, that time will come sooner in an inconvenient than in a convenient clinic, and the additional running costs will quickly exceed the initial saving.

For the guidance of local authorities the Ministry of Health have approved the building of a model clinic at St. Thomas' Hospital and have also prepared type plans of clinics arranged as they think will prove most convenient. There are two type plans for huts or rooms of different sizes and I should like to explain the principles and method of running a center planned on these lines.

Principles and Working Method

The plans printed herewith are arranged according to the type approved by the Ministry of Health for a sixty by thirty foot hut. It will be found that the principles of the arrangement shown in the type plan can often be adapted to existing buildings.

Male patients are handled as follows: On arrival, each patient reports at the inquiry window of the clerk's office. He may be (1) A new patient; (2) an old patient attending for anti-syphilitic treatment; (3) an old patient suffering from gonorrhea, and attending for examination by a medical officer; or (4) a gonorrheal case attending for irrigation. In the case of (1) the particulars are entered in the confidential register, the patient receives a ticket showing his identification number, a treatment card is made out for him, and he is directed to one of the examination

cubicles shown on the plan. The examination cubicle is reached by the patient via the passage shown on the plan, and no patient is permitted to enter the service and general room. On reaching the cubicle, the patient undresses sufficiently for a complete examination to be made, and is then examined by a medical officer. Each examination cubicle is closed by seven foot high partitions on three sides and is open on the fourth side. On this side, as shown in the plan, is a counter two feet eight inches high and one foot four inches broad which is upholstered so as to serve as an examination couch if required.¹

Access by the medical officer to the cubicle is obtained by lifting a flap in the counter. The fourth side can be closed by a curtain if desired. The furniture of each cubicle consists of: (i) A small writing table on which are all stationery requirements; (ii) An instrument table on which are all the instruments for taking specimens and for making an ordinary examination; (iii) A double basin, portable wash-hand stand with perchlorid lotion above, in which to sterilize hands, and carbolic or lysol below for used instruments; and (iv) A rack holding four urine glasses.

The cubicle equipment is supplemented by equipment for special examinations and treatment, which is carried on trolleys standing in the service and general room. This supplementary equipment is grouped according to its purpose. Thus there are (i) A minor operation and dressing trolley, holding all the instruments, etc., required for dealing with a case of, e.g., bubo; (ii) A gonorrhea trolley containing all the instruments required for special examination of a case of gonorrhea, including urethroscope and rheostat, the latter working from an electric wall socket in a partition of each cubicle; and (iii) Mercurial injection, arsenobenzol and urine-testing trolleys.

If a medical officer requires special instruments other than those which form the normal equipment of an examination cubicle, he calls up the

1. The plan shows this counter set too far into the cubicle; it should be one foot nearer to the service room, i. e. the front edges of the counter should be in line with the ends of the cubicle partitions.

*Paper presented before the North European Conference on Venereal Diseases, Copenhagen, May 20-25, 1921.

The plan of a venereal disease clinic of the type used by the Ministry of Health, and one that can readily be adapted to existing buildings.

appropriate trolley, which stands, while in use, outside the cubicle, alongside the counter or examination couch.

The result of these arrangements is that neither patient nor medical officer need leave the cubicle from beginning to end of the examination, except when the medical officer wishes to examine a microscopical specimen. This is done at the bench in the service and general room.

(b) In the case of patients attending for anti-syphilitic treatment the routine is as follows: (i) Anti-syphilitic injections are given at set hours, though new cases are injected at once. (ii) Each patient is first interviewed and examined in the doctor's room and receives a slip on which is written the dose to be injected. He is then sent to one of the examination cubicles, these being filled at the rate of four or five to each cubicle. (iii) Each patient passes his urine. (iv) All urines are tested by an orderly passing from cubicle to cubicle with a trolley carrying urine-testing apparatus. (v) A medical officer follows with a trolley holding the arsenobenzol injection syringes and gives the injections. For this purpose the patient sits in a chair within the cubicle and lays his arm out over the counter conveniently for the medical officer, who stands outside the cubicle. (vi) Another medical officer follows with the mercurial trolley. (vii) The cubicles empty in turn as the trolleys proceed along the line of cubicles, so that, by the time the last cubicle is finished, the first has filled with a fresh batch of patients, and so on until all have been treated.

(c) Patients attending for treatment for gonorrhea by the medical officer may require only a minor examination, in which case they are sent into the minor examination room adjoining the consulting room; or a more detailed examination, which is

carried out in one of the examination cubicles.

(d) Patients attending for irrigation receive a pink ticket on which are written the details of the irrigation required. The patient takes his pink ticket to one of the irrigation cubicles shown on the plan, and the orderly working at the bench in the service and general room supplies solution, nozzle, and, if required, assistance for the irrigation ordered. Each cubicle is fitted with hot and cold water so that, for most types of irrigation, the orderly need bring to the cubicle only the concentrated solution and the nozzle.²

Care of Female Patients

If the premises are required for both male and female patients, it is necessary (1) To add to the furniture of each of the three examination cubicles on the right a gynecological examination chair, and (2) to curtain off about two feet of the back end of the cubicle in order to provide a small dressing space for the patient. When the patient is under examination on the chair, this curtain can be withdrawn to allow the operator more room.

It is an advantage, if the available space will allow, to make the cubicles eleven feet deep, rather than ten feet as shown in the plan, in order to allow for the additional space taken up by the examination chair and by the curtained-off dressing space at the back of the cubicle. If the counter is set one foot nearer to the service room than is shown on the plan, as already suggested, the free available depth is then seven feet eight inches to the dressing curtain, and nine feet eight inches if this curtain is withdrawn during an examination.

It will be seen that the main principles of the clinic are that

(i) The staff works on internal

² It has been found in practice that the counter shown in the irrigation cubicles on the type plan is not necessary.

lines and has ready access to every part of the clinic. Thus anyone standing in the service and general room can see the greater part of the clinic, and the staff is almost entirely within view. Also, the distance to be walked by any member of the staff is comparatively small and his passage is unimpeded by any door.

(ii) The patients are examined and treated in reasonable privacy without thereby interfering with the working of the clinic. This and other advantages are secured by making the patients use the passage on the outside and never permitting them to enter the service and general room. It is easy, also, with this arrangement to give demonstrations to students since the patient lies on the counter and most of the class stand in the service and general room.

It is important that every clinic should be arranged so that (a) intermediate treatment of both sexes may proceed at the same time, or (b) that intermediate treatment of males may proceed during the hours of female sessions. In order to carry out this principle all that is necessary is to (1) put a door in the passage at the junction of the examination cubicle which adjoins the irrigation cubicle with the examination cubicle next to it. (2) Carry the partition between this examination cubicle and the next to the ceiling, or roof. (3) Curtain off the service and general room so as to divide the clinic into two, the portion on the left consisting of the irrigation cubicles and the last examination cubicle, and that on the right consisting of the remainder of the clinic. (4) Provide an additional sink on the bench in the service and general room to the left of the curtain just mentioned. In this way, during a female session, the door would be closed and the curtains drawn, so that males could enter at the door on the left of the plan, and be irrigated without being visible from the remainder of the clinic. Also, any male patient requiring a special examination during the hours of a female session could be seen in the last examination cubicle. (5) Provide an additional W.C., for male patients, at the left of the plan.

In the case of the 60 foot by 15 foot type plan the principles and method of working are the same as those described above.

I should like to add a few particulars regarding the recording of particulars. The Ministry of Health requires the particulars to be returned in Record Form V. R. 10. At St. Thomas' Hospital the arrangements

A law passed at the last session of the legislature provides that the assistant commissioner of the Department of Labor and Industries shall be a woman. The assistant commissioner is permitted by the act to inspect industrial establishments to determine compliance with the labor laws, and to make investigations concerning the conditions of employment of women and children.

The Ethics of Health and Medical Advertising

WITH unfailing regularity the much mooted question of the propriety of health and medical advertising rises to the surface and with almost equal precision it is submerged after the usual "ethical reasons" are offered. No one can doubt the wisdom of medical ethics which insures high professional standards, and the oath of Hippocrates will ever be remembered for its gospel of high idealism.

Conditions today are not comparable to those of centuries ago. Medicine is no longer considered a dark and occult science whose mysteries are uncovered to a select few. Public health has the enlightened interest and understanding of a much larger group who constantly seek new knowledge on health and disease. Because of the apparent failure of the legitimate teachers of health—the medical profession—to satisfy this demand, the general public has become an easy prey to the malicious and unscrupulous advertising of the medical quack and patent medicine fakir who are ready to grasp every opportunity to further their own selfish designs.

Assuming that the physician in private practice has no proper outlet for making known his services through the usual advertising mediums, it does not follow that the medical profession, through societies or group practice should not utilize publicity to keep the public informed of the progress of scientific medicine or the highly

specialized services which a clinic, hospital, or other medical group is prepared to render. Or if one insists on subduing this phase of medical advertising, why not emphasize important truths about such vital subjects as food, exercise, fresh air, and physical examination?

Medical groups do not hesitate to inaugurate extensive advertising campaigns to influence legislation affecting the various cults or their own practice, probably because of fear of professional encroachment as well as desire to protect the public. The fact is, there is a field for legitimate health and medical advertising and until this is recognized and satisfied by the medical profession, the craving public will continue to consume the vicious matter of the unscrupulous quacks who have so long monopolized the field.

Philanthropic Doubt Should Temper Social Enthusiasm

FOR thirty years the philanthropists of America have indulged in a perfect "orgy of charitable activity. They have developed and expanded every form of humanitarian service common to the civilized nations, and have searched the world and their own imaginations for types of moral and physical ailment to which the philanthropies of old were oblivious, in order that they might still further improve society, and have even wider openings for the spread of their social enthusiasms," states Cornelia J. Cannon in the *Atlantic Monthly* for September, 1921, in an inquiry into the present status of American philanthropic endeavor. To be fully appreciated the article should be read *in toto*. We shall merely call attention to some of the most salient features of her discussion.

Her first inquiry is into the motive of the philanthropic impulse. This is not brotherly love nor friendship, but is an extremely complex impulse in which are mixed elements of kindly condescension, sympathetic fellow feeling, and ardent generosity. In many cases of applied philanthropies there is, however, unquestionably another motive, and that is to give back as a salve to the conscience some of the wealth which modern industry has permitted a few to accumulate at the expense of the many.

One of the conditions to which Mrs. Cannon calls attention is the lack of proper concept by the philanthropist of the state of mind of the person helped. Rarely is the human side of the person to be helped seriously enough considered by the philanthropist, even though the social worker, who is the technician on the job, is gradually coming to see the necessity of basing all work on the fundamental study of the reason for the work. "We

should regard as an impertinence, if done to us, the invasion of spiritual privacy that the more tolerant victims of misfortune accept as part of their disability. They act upon our advice if they must, they disregard it if they can, but they preserve untouched the inner citadel of their personality."

Despite the war and the fact that during the war the need for philanthropies was cut to a comparatively small proportion of its pre-war basis, Mrs. Cannon believes that the various organizations have failed to learn that some of them may not be needed. The intense individualism of each unit, jealous disregard of the virtues of one another, are often responsible for keeping alive institutions which have served their day. Perpetual endowments still exist and "give immortality to the normally transitory." More recent experience in some fields of social activity, however, show that certain organizations at least have begun to ask themselves the question, "Are we needed?" Although we agree with Mrs. Cannon in a general proposition, we feel that a statistical study would show that her thought has been forestalled by some organizations.

The next big question discussed by Mrs. Cannon concerns the essential nature of the work of the philanthropic societies. She doubts, as many before have doubted, whether most philanthropic societies are doing an essential work or whether they are just applying salve to sores. The application of palliatives, maintaining and patching up of society, does not get very far. What modern philanthropic effort needs is the same sort of application of psychological research that Parker applied to the study of economic conditions. We feel that until a profound application of psychological methods is made most philanthropy will be merely mending.

Now, if this condition of affairs is true, Mrs. Cannon naturally asks, "What is the cure?" As we see her argument, the cure lies in a fundamental change of method. Private philanthropy has use only as an experimental station for the development of methods which, when proved successful, should be turned over to the community.

Responsibility for evils of mankind should be shouldered by the whole community. The effort, time, and money now being spent by private agencies should be diverted to improvement of existing public agencies. Public officials, says Mrs. Cannon, are not as bad as they are painted and, if a closer contact were striven for, public control would result in better care. As examples of the shift from private to community interests, attention is called to the work on tuberculosis, legal aid for the poor, kindergartens, workmen's compensation acts, and the mothers' pension acts.

All the burdens formerly carried by private agencies have been shifted to the tax payer, in some instances at least with a vastly improved final result.

Naturally, a thoughtful and scholarly discussion such as that of Mrs. Cannon does not end here. The fundamental causes of distress must be sought out, studied, and prevented. Unemployment and illness are the two great causes of social disturbance requiring aid. The final remedy then is the prevention of poverty and illness. This job belongs to the community and not to the private individual.

The Rise and Fall of Umbilicology— A Note on Ultraspecialism

WHEN F. X. d'Illon, the famous umbilicologist, graduated from medical school he was simply Frank Dillon, the tall, black haired son of a switchman in the C and I railroad yards. He was not a particularly good student but he had an unusually convincing conversational line and was the Poker Medalist of his class.

Completing his internship, he early discovered that many names beginning with D are of French origin, so he stepped down his patronymic initial and inserted an apostrophe, emerging as d'Illon.

It was apparent, even to a mind less acute to the main chance than d'Illon's that the staid and plodding road to success in general medicine and surgery was weary, toilsome traveling and that quackery, while more immediately successful, ended inevitably in disaster. So he decided to take up a specialty.

Carefully scanning the field, he was at first dismayed to find that practically every anatomical region had been pre-empted and colonized and that the realms of special operative procedures and diagnostic manipulations were already well populated. His search however was not unavailing and for a time he wavered between diseases of the umbilicus and ingrowing toenail, finally choosing the former. Besides, umbilicologist sounded well and there was an excellent treatise on diseases of the umbilicus just off the press.

His next step was to present to the local medical society a modest paper on "The Relation of Umbilical Nystagmus to the Pampiniform-Plexus." This achieved an instantaneous hit, in fact, several of the older members said it was a scream. At any rate, he paid the postage on a thousand reprints, receiving in return a choice collection of form letter acknowledgements.

This emboldened him to treat the State Medical Society to "The Umbilicus and Freudism" and the Conference of County Health Officers listened pa-

tiently to "Hygiene of the Umbilicus,—a Plea for its Inclusion in Public School Curricula." He received a complimentary letter about this from the superintendent of the Naval Academy.

His connection with the Municipal Clinic made it possible to keep his well furnished waiting room fairly full during office hours and before long pay patients began to drift in. Several constipated society women were much relieved by his method of vibratory umbilical massage, combined with exercise and certain dietary changes. He filled a few off hours in the schedule of the medical college with lectures on his growing specialty. His "Degenerative Umbilicitis and Home Brew" was a classic.

Chinless apostles gathered round him and he founded the American Academy of Umbilicology, electing several unsuspecting foreigners to honorary and corresponding fellowships. The transactions were printed and a publisher was inveigled into issuing the Quarterly Journal of Umbilicology. Later this company failed.

The time was now ripe for an International Congress, with d'Illon as president and his assistant as secretary general. A wealthy manufacturer of patent surcingles financed the Congress. Unfortunately he passed to his reward the following year. The sanatorium authorities said it was general paresis but d'Illon always insisted that convergent umbilical strabismus carried him off.

A General Committee of One Hundred was formed and the appointments were sent out to a carefully selected list of prominent men. The secretaries of several sent in stereotyped acceptances. A hardshell Baptist wrote that although he was a conchologist he would serve anyway.

While the Congress did not have a large attendance, it certainly was a select gathering. The presidential address on "The Future of Umbilicology" was well received although many felt that perhaps the criticisms of the War Department for refusing to detail an umbilicologist to the General Staff, while merited, were harsh. Resolutions of condolence were passed over the death of the President of the Naval War College and a memorial was addressed to Congress urging the creation of a Department of Umbilicology with a seat in the Cabinet. The fees for the Congress almost paid for the reprint of d'Illon's address.

Two winters later while swimming from his steam yacht at Palm Beach the Father of Umbilicology was eaten by a cannibalist shark. Later his remains were found in the interior of the shark, which swam ashore and died, evidently of disgust. Thus rudely deprived of its leader, umbilicology retrograded. In fact, it is to a considerable degree being overshadowed by onyxizology under the brilliant fatherhood of d'Avis.

Target Patterns for Accuracy in Sanitary Campaigns

THE "marvelous advance of sanitary science" is a phrase too frequently met, carrying with it a sort of finality and leaving the impression that, while there may be a few rough corners here and there to be chiseled off, the statue of Hygeia is rapidly nearing completion. Worst of all, it fosters a complacency in the average half-baked sanitarian and the ready acceptance of things merely on the basis of the printed word, without definite tangible proof. As a result, disease eradication campaigns have been frequently based on wholly inconclusive evidence.

For example, "Do not spit; to do so may spread disease," is a conservative statement, carefully modified by the subjunctive "may." The average mind reads this: "Spitting Spreads Sickness." But do we *know* that spitting ever spreads disease? If so, what diseases are known definitely to be disseminated by careless spitters?

Witness the propaganda literature regarding influenza and recall the masking of whole cities so that the inhabitants thereof should not infect one another by spray nozzle coughing. Is it proved that droplet infection ever caused influenza or that a dog muzzle which would keep the fingers out of the mouth might not have been quite as valuable a prophylactic instrument as the cheese-cloth mask? If sputum is the vector in so many diseases, why do so many enthusiastic adherents of the sputum commerce dogma pass over unnoticed the unsterilized eating utensils of the public restaurants? Do we *know* that careless spitting spreads tuberculosis and for that matter do we *know* that adults ever contract tuberculosis?

Have we any definite knowledge of how poliomyelitis is spread, i.e., have we the knowledge on which to carry out accurate defensive and offensive operations? How great is our definite accumulation of facts regarding the rôle of the carrier in meningitis spread? Do we know how to differentiate between virulent and avirulent meningococcus carriers?

As a matter of fact, are we not spending great sums on disinfections and house quarantines which are warranted only by presumptive evidence?

"Presumptive evidence," is that not the basis of a great deal of the sanitary work which is now going on? In other words are we not hunting disease with a blunderbuss instead of an accurately aimed rifle? And while we are scoring hits in this way are we not causing the tax payer unnecessary inconvenience and expense. If this is doubted by the reader, let him scan with an

open and inquiring mind the sanitary code and regulations of any city or state and let him ask himself how much of the material therein rests on well established fact and how much upon precedent and upon that ignorance which does more than is necessary because it must make a big target in order to strike a given point.

Doubtless, sanitary science can never achieve a mathematical precision—too many variants, too many human factors are involved in the equation of disease—but the control of typhoid and yellow fever are striking examples of the accuracy which can be reached. These warrant the hope that under the stimulus of a healthy scientific skepticism, the prevention and control of other diseases may be reduced to the least common denominator of actual fact.

In the meantime, it is a consolation to remember that the blunderbuss is one of the evolutionary phases toward the rifle. The point of the story is to recognize it as *ye olde* bell-mouthed smooth bore, and not to delude ourselves as to its accuracy or muzzle velocity. Of course, its use must continue until research produces a better weapon.

Some Unrecognized Industrial Danger Signals

THE general manager of a large manufacturing plant told this story: "The other day one of our steadiest mechanics shot himself. Apparently there wasn't a reason in the world; his family life was happy; he was not dissipated; he was a quiet, hard-working man. His foreman reported that he had only one peculiarity; no matter how good a piece of work he turned out, he always belittled it, comparing it with the jobs his father used to do, regretting the relative inferiority of his output. I talked the case over with our shop doctor and he told me a lot about 'sense of inferiority' which I understood, and threw in a lot more which I didn't.

"At any rate, it started me to thinking about several cases we had had in our plant. I recalled a man who had been driving a shop-mule,—a cracking good man with a record for reliability and carefulness. All at once, he began hitting things and had a series of small accidents, winding up with a grand smash-up which killed one man and injured several others pretty badly. We fired him, and he landed in an insane asylum, where he died about a year afterwards. Then there was a foreman in the woodworking plant, a good, sober man, full of energy, apparently a comer. He began getting rough with the men and at first I thought it was just his way of hurrying up production. Then he went over into the foundry and tried to tell our foreman molder

how to do things, got into a fight, and spent a week in the hospital. From that he went from bad to worse, got to drinking bootleg whisky, and we had to let him out. He died about eighteen months afterwards, crazy.

"I could go on and tell about a good many cases I've come across in our office force and sales staff cases which are clear enough to me now after twenty years of experience and a tip from our doctor. The point is this: why didn't I recognize what was going on at the time? Why was it necessary to let these people go on to destruction before somebody realized that something was wrong? Of course, we have been paying attention to these things only a few years, and, of course, if we had brought these cases to the dispensary the doctor would have discovered what was wrong; but we didn't send the men in because we had no idea that they were going wrong. There were danger signals sticking out all over them, but we didn't see them because we didn't know that the man who suddenly changes his ways or who becomes queer is a danger to himself and everybody in the plant.

"It strikes me that what we need is a little instruction along these lines. I don't want my foremen trained so that they could qualify as expert witnesses in a murder trial, but I wish somebody would describe the danger signals in garden-variety language that could be understood by those in close contact with the man on the job. If the foreman could understand that the skillful man who suddenly gets clumsy, the meek man who all at once becomes chesty, and the steady church-goer who takes to high-power swearing, should make a trip to the doctor, I believe our plant and its employees would be a good deal better off. They tell me, too, that a lot of these men may be salvaged; at any rate their chances of being scrapped would be much reduced."

Health Work Receives Impetus at Harvard

IN ITS Department of Industrial Hygiene and other laboratories Harvard has long afforded opportunities for study to those medical and health workers who felt the need of definite training for work in special fields, but the gift of \$1,785,000 recently made by the Rockefeller Foundation makes possible the establishment of a school for public health officers at Harvard with provision for additional aid should growth and development of the project require it.

Methods of teaching will be improved and facilities afforded whereby medical students, physicians, sanitary engineers, and other related specialists may have the special training which

will fit them for public health work, and means will be provided by which an adequate number of efficient men may be made available to fill the crying need of such workers. Education of the general public may also be expected to keep pace with improved health officials and that background of enlightened public opinion fostered which is the ultimate safeguard in matters of health administration.

Named in the order of their establishment, there are now ten schools in the United States for the training of public health officers: The University of Pennsylvania; Harvard University; Universities of Wisconsin, Michigan, and California; Detroit College of Medicine and Surgery; University and Bellevue Medical College; Yale Medical College; and Albany Medical College. The School of Hygiene and Public Health, established at Johns Hopkins Medical School in 1916, is the only other school of public health to receive the benefaction of the Rockefeller Foundation.

THE dedication exercises of the Peking Union Medical College which took place on September 19, attended by a highly representative group of American men of science, afforded a dramatic contrast between the methods of preventive medicine of the western world and the traditional attitude of apathy and fatalism exhibited by the Chinese.

China from time immemorial has had practitioners in the healing arts, but they always rely upon mysticism, are subject to no legal restraint, and are required to present no credentials as to qualifications. Among a people content to be treated according to precepts dating back for centuries, the Medical Board of the Rockefeller Foundation has established laboratories for research, hospitals for medical service and training, and an out-patient department for the extension of service among the people.

While this is an enterprise calling for the utmost scientific optimism, it offers the only feasible chance of bringing a backward people into an inquiring state of mind. They cannot be expected to lift the veil and see for themselves the direct relation between cause and effect until they are taught to look forward instead of backward. This ocular demonstration in health work and scientific inquiry will serve humanity and, incidentally, the boundaries of science will be extended.

THE Child Health Organization is responsible for the plan outlined in a government pamphlet which is to constitute the basis of work with school children which has as its object the training of the whole childhood of the Nation

not only in theories of health, but in health habits. If this plan is carried into effect, says the Bureau, school children will not stop with theory, but will actually become healthy.

The plan recognizes every agency for better health, but the onus of the work is placed on the teacher whose responsibility it is to train the child in health habits. The recommendations include thorough physical examination for every child at school entrance; individual health training through all the grades; each child weighed and measured regularly; height and weight records sent to parents regularly; health seeking made enjoyable by means of health clubs, rhymes, posters, songs, contests, plays; a definite time assigned to health teaching; plenty of exercise and play outdoors; cooperation between teacher, parents, community, school nurses, and doctors.

The children are furnished the "rules of the health game." The principle is sound, as it looks for its success to the interest aroused in the children themselves. The plan is flexible enough to be adapted to local needs, and positive results may be expected, looking toward the marked reduction of the high degree of physical disability that is now charged to the American child.

A FOUNDATION is being sought in England to make permanent the extra-mural work of the universities which has been carried into industrial districts by means of specially trained professors who become residents of university centers successively over periods of four or five years. The Viscount Haldane, who speaks authoritatively in such matters, has checked the results and reports favorably on stabilizing the plan to make the work permanent.

The whole matter suggests that the adult population, particularly the laboring classes, whose education is in the majority of cases terminated around the age of fourteen years, can and should be inducted into the larger outlook and the sense of freedom which knowledge brings. Where the opportunity for continued work is extended, freshness and originality of ideas has marked their progress. Their leisure time has taken on a new significance and the restlessness and discontent of minds without resource have been observed to give way to new interests.

Surely such advantages need to be made available on a large scale, and systematic courses in industrial extension centers should replace the isolated popular lecture. If any appreciable part of the programs planned for the betterment of industrial working conditions is to take root, it must be accomplished through the enlightened self-interest of the men themselves.

Relationships of the Insurance Practitioner

The Specialty of Industrial Medicine Is the
Product of Important Community Relationships.

By GEORGE E. TUCKER, M.D., MEDICAL DIRECTOR, AETNA LIFE INSURANCE COMPANY, HARTFORD, CONN.

AN INSURANCE practitioner may be defined as a physician, or surgeon, who devotes an appreciable part or all of his time to the care of injured industrial workers and is reimbursed for such services by one or more insurance companies.

The adoption of workmen's compensation insurance laws by the several states created a new field for specialization, and the so-called insurance practitioner is undertaking to fit himself to practice successfully in this field of medicine and surgery. The development of this specialty is the direct outcome of a study of the experience of approximately ten years' administration of medical and hospital benefits under these laws.

A New Specialization

The unsatisfactory results that have been obtained from the indiscriminate reference of cases of industrial injury to general practitioners made it necessary to adopt administrative measures that would in part overcome this practice.

Likewise, the experience of well organized self-insurers clearly showed that physicians in industry provided intelligent care of injured workers through utilization of those superior medical and hospital facilities that their training and investigation enabled them to select.

Prior to 1911, or during the years that industrial injuries were looked upon as an unpreventable by-product of industrial activity, a part of the

Insurance as a method of distributing the burden of sickness and disability has gradually replaced the indiscriminate handling in free clinics of cases involving industrial conditions by the special clinic with precisely adapted methods.

Specific records, correlated observation, concentration and volume of practice led to the development of specially trained men, and the best practice in this field constitutes a dignified specialty in which earnest adherence to the fundamental rules of professional ethics will allay unfair competition and tend to still invidious criticism.

burden of the cost of repair and replacement of the injured in industry was distributed to the community through its maintenance of free clinics and dispensaries, patronized so largely by industrial workers.

These institutions were conducted as charitable enterprises and often utilized by colleges for teaching purposes. Their staffs were carefully selected and the cases were intelligently distributed among the several groups of specialists. Cases of imbedded foreign body in the eye were not treated by internists; patients with palmar cellulitis did not receive expectant treatment from obstetricians.

So-called "clinic" patients enjoyed such obviously superior service that the oft repeated statement that "only the very rich and the very poor have the best medical and surgical attention available," was demonstrably true.

With the advent of the new social relief legislation and its provisions for the more equitable distribution of the burden of cost of industrial injuries, came fees for both physicians and hospitals to care for that group of industrial cases that had previously been dependent upon the services of the free clinic.

Likewise, fees became available for treating minor injuries of the type that had previously been subjected to home remedies or to the unskilled care of the voluntary first-aiders.

Legislators early contemplated and often publicly stated that workmen's compensation laws were designed for the benefit of the working men and women whose occupations brought them within the scope of such laws. Later, with somewhat less emphasis and more hesitancy, they argued that such laws would prove to be of benefit to employers and to the community. Never, to my knowledge, have legislators generally urged the passage of a compensation act on the ground that it was intended to be a measure designed for the benefit of the medical profession. On the other hand, no discrimination was intended; so, if the medical profession received fees neither more nor less than those

they previously enjoyed from the same class of patients under the provisions and administration of a compensation act, the charge of unfair or unjust discrimination could not be successfully sustained.

The apparent interest of the rank and file of the medical profession in social relief legislation or in those to be relieved came too late to exert any modifying influence on its provisions, and even during more recent years the occasional outburst of professional protest has been directed toward raising the maximum fees and providing free choice of physicians, rather than toward bringing about the passage of amendments that would have the effect of reducing accident frequency and accident costs.

Addressing my remarks to physicians in industry, it is unnecessary to point out either the advantage or the need for the careful and intelligent distribution of injured workers to well selected medical attendants.

A Question of Efficiency

Your greatest service to your employers and your industries, in connection with the proper handling of the industrially injured, results from the kind of treatment you provide through yourselves or your associated staff of doctors and nurses and the supplemental assistance you obtain from available specialists in their several fields.

As a rule, general surgeons make a mess of the treatment of flat feet, and orthopedists obtain equally poor results when they undertake the radical cure for hernia, while general practitioners with limited knowledge of orthopedics and surgery obtain less satisfactory results than either.

Insurance practitioners are engaged in several varieties of work. There are those who confine their activities to problems of administration; others limit their practice to physical examination of workers and treatment of minor injuries; while still others are specialists in the several recognized specialties.

Physicians engaged in administrative work serve insurance companies in the capacity of medical directors or medical referees and are assigned to duty in territories where the volume of business justifies their employment in this branch of service. Their contact with the community and with industry is largely in an advisory capacity, giving attention to accident prevention, reduction of time lost from industrial injuries and the solution of those problems in industry that have to do with occupational disease hazards.

The physician or surgeon who is undertaking to limit his general practice and confine his activities to the care of the industrially injured is in most instances paid for part or all of his time on a per capita fee basis, and his successful bid for this business is based upon the superior methods which he employs and the administrative facilities that he maintains.

The average physician dislikes keeping records and giving attention to those features of so-called "routine" that are so essential in the proper conduct of insurance business, and the average physician's office is poorly equipped to carry on this work. Likewise, the community practitioner hesitates to involve himself in the overhead expense incident to employing an assistant in order that surgical services may become readily available during any hour of the day or night.

The proper treatment of injured workers contemplates twenty-four hour service and the maintenance of unusual consultation hours becomes necessary in order to meet the demand of both time and piece workers who hesitate to lose the income incident to being away from work to receive treatment during the regular office hours.

A concentration of this particular type of work permits the insurance practitioner to maintain facilities and to purchase equipment for proper treatment that is not found in the usual doctor's office, and since this service confers a benefit upon that portion of the community entitled to receive it, and since the reduced lost time increases production and lowers cost not only to industry but to insuring companies, the physician who is competent and desirous of undertaking this work is worthy of every encouragement that concentration of business and adequate pay affords.

In this field of specialization there are a great many orthopedists, ophthalmologists, and physiotherapists who devote practically all of their time to the care of injured workers for insurance companies, and such practice has proved to be not only lucrative, but highly satisfactory from the professional standpoint, and just so long as their services are founded on a basis that will insure them a reasonable return for the amount and character of services rendered, their economic relationship to their patients and to the medical profession at large does not differ from that of specialists who only incidentally treat this same class of persons.

The possible development of a system of contract practice, with all of its attending evils, has been most studiously avoided both by the best insurance companies, and the more desirable practitioners. Large railroad companies, manufacturing enterprises, and the United States Government have long employed physicians on the basis of whole or part time employment, therefore, insurance companies have followed a well established precedent when they adopted similar plans that were no longer experimental.

Small enterprises are not prepared to maintain medical facilities comparable to those found in the larger better organized industries, and since there are 7,036,336 workers in the United States employed by manufacturing concerns, and only 648 plants having more than one thousand employees, to reach that very important and very large number, facilities established by insurance companies to meet the needs of the small groups serve a very useful and desirable purpose.

In the same manner, emergency hospitals with full time attendants, located so as to provide treatment for injured employees of small plants, fill a need that is seldom met by cooperative effort, except through the agency of insurance companies.

If we would encourage immediate and skilled treatment for large numbers of injured workers and a minimum disability with a minimum loss of time, organized first aid facilities, proper referring of major injuries, and concentration of work in centrally located establishments must supersede the unorganized "catch-as-catch-can" system that was so universally in vogue prior to the advent of the physician in industry and the insurance practitioner.

The first intelligent effort that was made to record the result of the application of medical and surgical skill as it affects functional recovery and occupational earning power has followed the establishment of medical departments in industry and a study of workmen's compensation cases.

It is much easier to determine who in the community obtains the best results than it is to learn how such results are accomplished. As anomalous as it may seem to the uninitiated, the surgeon who enjoys the best reputation and the largest income, or the most lucrative practice, does not uniformly bring about the rehabilitation of the worker and his return to normal earning power in the least time.

How and when to immobilize a fracture may assume less importance than the question as to how long immobilization should be permitted to continue. The determination as to when a worker is prepared to return to work and a knowledge of the industry that enables the attending physician to determine in what occupation he may safely engage is oftentimes quite as much a part of successful treatment as is the choice of therapeutic methods to be employed.

A knowledge of the relationship of certain nationality groups to suggestions, of their prejudices, and of their tendency to obey or disobey instructions, is indispensable to the medical attendant if he would practice successfully among these groups. Contact with only the occasional case does not permit of the development of this information, whereas, concentration and volume accords this desirable opportunity.

Both insurance and industrial practice permit of observation and the development of technical skill not unlike that obtained by surgeons who enjoy operating in large clinics in connection with institutional teaching.

To learn to so describe an injury as to convey an accurate picture to a claim department and to the administrative bodies of industrial accident commissions becomes a necessary part of the insurance practitioner's education. He cannot be satisfied with a report that merely states that "a foreign body was found in the eye." To him the term "laceration on the back of the hand" does not indicate the seriousness of the wound.

The use of indefinite terms and the submission of incomplete and inaccurate information constitutes a source of annoyance that can only be overcome by education of very large numbers of physicians who undertake the care of compensation cases, and the success that has attended the efforts that have been made by various agencies during the last ten years has not been encouraging. Repeated requests to physicians for additional information are not usually well received, and hypersensitiveness is not a trait unknown to members of the medical profession.

Insurance companies are not trying to develop a group of physicians in their own employ at the expense of the advancement of the private practitioners, but they are undertaking to make the field of insurance work so inviting as to attract high grade practitioners to it, so that specialization in this type of practice will be equally

beneficial to industry, industrial workers, the community, insurance companies, and the private practitioners who follow this work.

Misunderstandings and jealousies will undoubtedly accompany the insurance practitioners' efforts to be successful, but earnest adherence on their part to the fundamental rules of ethics governing the profession and

an equal understanding and effort on the part of administrative representatives of insurance companies will ultimately develop that confidence of all parties concerned, which will permit of the cultivation of an amicable arrangement that will receive the hearty approbation of the medical profession, the worker, industry and the community.

ASSOCIATION LETTER

BY WILLIAM ALFRED SAWYER, SECRETARY

THE meeting of the A. A. I. P. and S. in conjunction with the Health Service Section of the National Safety Council was held in Boston, September 29th and 30th. The papers presented were of a high order and well received by a goodly attendance. Of particular merit were the papers on "The Problem of Heart Diseases in Industrial Workers," by Dr. Paul White, with its discussion; "Infection of Industrial Injuries," by Dr. Frederick J. Cotton, with its discussion; and on "Injuries and Diseases giving Symptoms Especially Referable to the Lumbar Spine," by Dr. C. L. Bradford of Pittsburgh and Dr. Robert Osgood of Boston.

The Health Service Section passed a resolution to the effect that the papers presented before the Medical Section should be distributed among the other sections in order that material presented should reach a much larger percentage of the members attending the National Safety Council meeting. Ruling will be made on this in executive session of the National Safety Council.

A meeting of the Board of Directors for the American Association of Industrial Physicians and Surgeons was held in Boston Thursday evening, at the Copley-Plaza Hotel, with the following officers and directors in attendance: Doctors C. E. Ford, C. F. N. Schram, L. A. Shoudy, R. E. Elliott, William Alfred Sawyer, G. H. McKinstry, C. H. Watson, and P. H. Hourigam.

The Board was in session for three hours and took up for discussion many matters of importance to the future of the Association, chief of which were plans for an increased membership campaign. Plans for this membership drive will be published and every effort made to enlist the cooperation of everyone now connected with the Association.

The Board of Directors voted to hold the next annual meeting at St.

Louis, Monday and Tuesday, May 22 and 23, 1922, the first two days of the meeting of the American Medical Association. Already some thought is being given to a program for these sessions. Dr. R. C. Quinby has been chosen to succeed Dr. Lauffer as director.

At the meeting of the Board of Directors the following committees were appointed:

Committee for the Coordination and Standardization of First Aid Methods to be Applied in Industry: Dr. L. A. Shoudy, Chairman, Dr. A. W. Colcord, Dr. F. L. Rector.

Committee to Evolve a Practical Scheme for Supplying Health Service in Small Plants: Dr. C. F. N. Schram, Dr. C. D. Selby, Dr. A. E. Shipley.

It is with pleasure that we introduce to the membership the following new members:

Dr. William Hall Bunn, National Lamp Works, Youngstown, O.

Dr. Frank C. Henry, Perth Amboy Hospital, Perth Amboy, N. J.

Dr. James F. Sullivan, National Lamp Works, Pawtucket, R. I.

Dr. Wm. F. Lyon, National Harvester Company, Akron, O.

Dr. Fred H. Harrison, 20 North Lee Street, Cumberland, Md.

Dr. Geo. Hoyt Bigelow, Antioch College, Yellow Springs, O.

Dr. Fred S. Caverly, 157 Passaic Street, Passaic, N. J.

Dr. A. O. Buck, Singer Manufacturing Company, Elizabeth, N. J.

Dr. D. L. Lynch, New England Telephone and Telegraph Company, Boston, Mass.

The tentative program for the industrial Hygiene Section of the American Public Health Association, which holds its annual meeting in New York City, November 14 to 18. All the members of the A. A. I. P. and S. who possibly can are urged to attend this convention as many points of interest and help to the industrial physician will be discussed. A series of valuable addresses are offered on industrial medicine.

The Industrial Physician and the Hospital

Recorded Observation and Correlated Effort Afford a Fertile Field for the Research Worker

BY HARRY LINENTHAL, M.D., PHYSICIAN TO OUT-PATIENTS, MASSACHUSETTS GENERAL HOSPITAL; INSTRUCTOR IN INDUSTRIAL MEDICINE, MEDICAL SCHOOL OF HARVARD UNIVERSITY, BOSTON.

THE opportunities for cooperation between the industrial physician and the hospital will depend in a large measure upon the individual physician and the scope of his work. The work of physicians in industry is greatly varied and may consist of from the administering surgical first aid in cases of industrial accidents to that of being the administrative head of a large health organization in an industrial plant. The beginning of the industrial physician's work was that of rendering first aid in injuries resulting from industrial accidents. From this beginning the work gradually has developed in many instances so that it now includes medical dispensary service to all employees; the detection of diseases in their incipency, whether the diseases be industrial in origin or not; the physical examination of those applying for employment so that the fitness of the employee for the particular job may be determined, thus rejecting the unfit before they start; periodical examination of employees in hazardous processes, to detect the early occurrence of industrial diseases; the supervision of the general sanitation of the plant; and the recommendation of protective devices against industrial hazards and accidents. The industrial physician is often required to give opinions on all questions that may arise relating to industrial hygiene or other health relations in industry.

Variation in Standards

Varied as is the work of the individual physician in industry we find an equally great variation in the standards and organization of different hospitals. The hospitals whose cooperation we shall consider of value to the industrial physician are those that have organized departments in the various specialties and are equipped with chemical, bacteriologic, pathologic, x-ray and medical laboratories. It is evident that the utilization of the diagnostic facilities of the hospital will depend upon the scope of the physician's work, the special hazards that may exist in the given industry, and the special problems that present themselves in his work.

Only when complete cooperation obtains between the industrial physician and the hospital on the one hand and the diagnostic group on the other will adequate service be rendered by industrial medicine.

Such affiliation will give great impetus to the important study of industrial toxicology. There will also result a scientific correlation between occupational conditions and disease in general.

Where interest has centered on specific industrial problems, improvement has invariably followed. The extension of such interest and the intelligent analysis of statistical studies will further illuminate the whole subject and make for better practice.

I shall touch but briefly upon the relations between the industrial physician and the hospital in the treatment of industrial accidents. The cooperation which may be required in this field is that of x-ray diagnosis. This, of course, can be had at the hospital but can also be obtained with ease elsewhere inasmuch as many industrial plants have their own x-ray departments, or private x-ray laboratories are available almost anywhere.

In this particular field the industrial physician is likely to contribute to the general surgeon methods and devices that will be time saving and reduce the period of incapacity. The hospital surgeon in dealing with injury is apt to regard the technical surgical problem involved and the ultimate perfect result. The time element does not enter as strongly as it should into his treatment. To the industrial surgeon, on the other hand, the economic question is of paramount importance. He is also striving for the method that will render the best ultimate result, but his constant concern is to return the man to his job in the shortest possible time. With this emphasis on the time saving problem the industrial surgeon will often develop methods and appliances

to be used in certain injuries which will be distinctly advantageous in shortening the period of disability.

Group Diagnosis in Industry

But the relation between hospital and industrial physician should be far more intimate and varied in the diagnosis and treatment of medical conditions, whether these are the results of industrial hazards or other causes. There are, as I have mentioned, many industrial plants in this country where dispensary service is offered to all the employees, whether the state of ill health is the result of the work or not. The industrial physician is thus often called upon to examine the worker and make a diagnosis even if he has nothing to do with the further treatment of the case. Instances where the industry has undertaken the care of the health of its employees outside of the plant, giving them treatment at their homes, if such exist at all, are rare. It is not at all improbable that this will be the line along which future development to preserve the health of the worker is to take place. Before consulting outside physicians, however, the worker comes to consult the physician of the plant. In many instances diagnosis of the condition by the industrial physician with his necessarily limited facilities is impossible. Laboratory examinations may have to be made and the opinions of several experts in special fields may be required. Clearly the worker is not in a position to pay for such services, yet such expert study may be absolutely necessary to reach a correct diagnosis in the given case. The charitable clinic in a general hospital with all its facilities in modern diagnostic methods, with its staff of experts in the various specialties, should be at the service of the industrial physician in the diagnosis, and, if necessary, in the treatment of the case. The relation between the industrial physician and hospital is in such instances precisely that of the private physicians practising among the poorer classes in the community who constantly send their cases to the hospital for expert study and opinion for which the patient is unable to pay; or it is the

relation between the practising physician and the consultation clinic to which he sends his cases who are able to pay a moderate fee to obtain a group diagnosis.

The physician employed in industries in which there are special hazards liable to produce specific industrial diseases can derive great help from the facilities existing in the hospital for study of those cases suspected to be suffering from those diseases in their incipency, inasmuch as in many instances considerable laboratory work and other special examinations are essential in their detection. The special facilities of the hospital for the investigation of specific occupational diseases can thus be made available to the industrial physician.

The gain from such cooperation will not be entirely on the part of the industrial physician but will also be of decided advantage to the hospital physician, for he will be brought in contact with the wide field of industrial health relations and with the broad social aspects of medicine. It is of course needless to call attention to the evident advantage to the patient from such cooperation who will get the benefit of all the modern methods of investigation in the diagnosis and treatment of his case.

Specific Industrial Studies

To have such cooperation between industry and hospital most effective it is presupposed that the hospital have a special interest in conditions of employment and industrial hazards, in other words that the hospital have a special clinic with physicians in charge who are interested in health problems in industry and in the possible etiologic relations of various health hazards.

In addition to the mutual advantages to the physician and hospital already mentioned, which will result from their cooperation, it is important to call attention to another field in which I believe the industrial physician is going to be of great help to the hospital. I refer to the further research of the effects of industry on health, which is one of the chief functions of the work of an industrial clinic in a general hospital.

Our lack of knowledge of the general effects of industry on health is due to our inaccurate records and inexact tabulations. It is true we have a good deal of definite knowledge of the specific industrial diseases, the occupational intoxications and infections, we are also able to recognize the etiologic value of such industrial

hazards as dust and fumes, postural strains, etc.

But what the effects are of certain occupations on health, the frequency of morbidity and mortality from certain common diseases among certain groups of operatives; the effects of the general stress of industry, the speeding up, the monotony, the general fatigue effects we know but very little.

Such additional knowledge is, I believe, to be obtained from the analysis of large numbers of records with a view of establishing a correlation between the occupations and the diseases.

It is only the tabulation of vast numbers of cases that will permit deductions as to the relative frequency of certain diseases among certain groups of workers.

That valuable information can be gained by such statistical studies and that facts of importance can be brought out which do not become obvious even in the careful handling and study of the individual case is illustrated in an analysis of even as small a number as 10,360 admissions of persons in industry to the Out-Patient Department of the Massachusetts General Hospital. Just to cite several instances:

In the 10,360 cases tabulated the diagnosis of gastric ulcer was made 79 times; 26 of these, or more than 34 per cent, occurred among workers in candy factories. The diagnosis of gallstones was made 46 times, 26 of these, or more than 56 per cent, occurred among the same group of workers. Yet the entire number of candy workers was 205, or less than 2 per cent of the number of admissions.

The above is the most striking instance of the analysis which has not yet been completed. There are other instances while less striking are nevertheless very significant. Thus for instance while only 1 per cent of admissions were engaged in agricultural pursuits, that group furnished 5.6 per cent of all cases of bronchial asthma. The clothing industry furnished only 2.5 per cent of admissions yet they furnished 8 per cent of the acute respiratory infections.

It can thus be seen that the analysis of even so small a number of cases gives figures which are of extreme interest. The careful correlation between occupation and morbidity and mortality figures are full of promise for the increase of our knowledge of the effects of occupation on health. Where is the research worker to look for his data?

The modern tendencies of development of industrial medicine point very definitely to the fact that the medical organization in industry is going to develop and play a far greater part in the future in the care and treatment of the employees, both within and without the industrial plant. In other words, industry, if we interpret the present trend of things correctly, will assume a greater and greater activity in the care of the health of the employees. This is a fact which the medical profession should realize inasmuch as such a development will affect not only the size of the hospital clinic but the extent of private practice, particularly of those physicians who practice in industrial communities. Desirable or not as such a development may be from the standpoint of the physician, it is not likely that the development in industry will be influenced or checked in any way by the private interests of the physician.

The Present Trend

With such a development of medicine in industry the hospital clientele of persons engaged in industry will gradually become smaller and smaller and will not be sufficient for statistical analysis. Every large plant with a well established medical organization will possess accurate data as to its own force of employees, but there will be no central agency which will be able to combine the data and experience of all the plants.

It seems to me that the Industrial Clinic because of its special interest in research in industrial problems and because of its intimate contact with industrial physicians through cooperation along the lines indicated above can well serve as a center where the experiences of all physicians in industrial plants can be collected and progress made in our knowledge of the effects of industry on health.

His own experience with certain groups of workers will be the great contribution the industrial physician can make to the hospital.

I may note in conclusion that we have not discussed here the basis upon which the cooperation between the industrial physician and the hospital is to take place. If the hospital, for instance, is to help the industrial physician either in diagnosis or treatment of industrial diseases or accidents, on what basis should such assistance be rendered? How is the hospital or the hospital physician to be compensated for such work? Clearly some equitable adjustment

will have to be arranged in such cases to preserve friendly cooperation and to avoid the antagonism of the pro-

fession in general. The abuse of hospital facilities and service of hospital physicians by industry will have

to be guarded against. Some equitable adjustment ought not to offer any special difficulty.

Our False Standards of Disability in Industry

Collaboration Is Needed to Bring Together the Specific Findings in Industrial Medicine

By W. IRVING CLARK, M.D., NORTON COMPANY, WORCESTER, MASS.

PHYSICAL examinations were introduced into industry in 1909. By 1913 many large factories had adopted them. The object of the physical examination from the first was to eliminate from the factory those whose physical or mental defects rendered them a danger to themselves, others, or property, and to place those defectives who did not come in this class at work for which they were physically competent. When physical examinations were first instituted there was no previous experience as a basis upon which to estimate the probable disability for work caused by any given defect.

Empirical Standards

Industrial physicians were obliged to base their ideas upon their observations in private or hospital practice, and upon the standards set by life insurance companies in their examinations. The latter played a strong part in shaping not only the type of examination but the significance of the findings. In short, those defects which cause question or rejection for life insurance, and those which appeared in a general hospital service, requiring repair, were considered to be the physical defects which required attention and which, if severe, should be the cause of rejection.

In 1915 the Conference Board of Physicians in Industry, representing twenty-four large factories, established for itself examination standards in reference to physical defects necessitating special attention and defining different degrees of these defects. These defects placed a worker as sub-standard and the following rule was adopted:

All second degree defects should be considered as sub-standard according to following schedule: All groups sub-standard for hernia (second degree or more); varicosities (second degree or more); flat feet (second degree or more); varicocele (second degree or more); hearing (second degree or more); vision (second degree or more).

Also the following: Arteriosclerosis; endocarditis; tuberculosis;

The scientific solution of the social problems of industry rests largely upon due consideration of physiological conditions as affecting the workmen.

While the basic physical requirements of the individual worker under specific conditions are fairly well understood, this knowledge has not generally been put to work.

Since health and precise adaptation govern both intensive production and the comfort of the workman, industrial medicine must become more precise and its service extended to all the domains of industry.

bronchitis (chronic); emphysema (chronic); asthma (chronic).

This classification has been used by members of the board up to date.

As a result of physical examinations, in many factories there has been a rather high percentage of defects classed severe enough to reject. Thus Mock in 1918 investigated ten large industries employing more than one hundred thousand regular employees and found that out of 118,900 applicants examined in one year 55.6 per cent had no disabilities of any moment, 34.7 per cent has disabilities that did not interfere with selected work and 9.7 per cent were rejected for work because of disabilities. In general 10 per cent of those examined failed to come up to the minimum standard.

The Secretary of the Conference Board of Physicians in Industry in the summer of 1920 made a very comprehensive investigation of the extent and methods used in making physical examinations of industrial workers. Reports were obtained from thirty-four plants, representing fifteen separate industries and a working force of 410,106. It was found that 4.6 per cent were rejected because of physical disability and, if those are

excluded who were rejected for special work, such as train men, crane men, and inspectors, in whom defective hearing was the cause of rejection, the average proportion of rejection was only 2.8 per cent.

In the author's clinic the rejections were 3.5 per cent for 1916 and 3.7 per cent for 1920, showing how stable the rejection percentage remains. Fifty per cent of those rejected are men who have severe eye defects. This makes it unsafe for them to go into a factory where there is abrasive dust because of the irritation and possible danger to their already impaired vision. Thus, if this special defect is omitted, 1.8 per cent only of the applicants would have been rejected. These figures are brought to your attention in order to show the present tendency to reduce the standards of rejection and to suggest that experience goes to show that in every large factory men with almost any type of defect can be placed at work. This is especially important in defects which have been previously considered a danger.

It is not at all sure, however, that we are paying enough attention to certain defects which have hitherto been overlooked and whose importance is just beginning to be recognized. The only real test is experience and it is difficult to get this concisely from a group large enough to be of value. Having no compilation of figures to which to refer, the writer will give the experience of his own clinic.

Defects Which Are Dangerous

Hernia.—We have not found already existing hernia an industrial defect leading to loss of time, operation, or compensation. Every case of hernia which has given trouble has been one which occurred during the working period in the factory and did not exist prior to hiring. For many years we have had from twenty-five to thirty men with old hernias, mostly fourth and fifth degree, inguinal type, doing work of all kinds.

The majority of these men wear trusses, but a number wear such supports irregularly. During the past ten years there has been but one case of strangulation among the workers, and that occurred outside of working hours. From this experience the author has come to believe that a hernia which has existed many years, which is retained by a truss, and which is recognized by the worker, is no bar to employment in any part of the factory, provided that work of a similar nature has been done by the applicant up to a week prior to hiring.

Varicosities: These are undoubtedly troublesome but seldom cause loss of time. Even varicose ulcers, when treated, do not prevent a man from doing almost any type of factory work. In fact, from the man's point of view, the accompanying eczema is much more of an annoyance than the varicose veins or even the ulcer. From a medical point of view the patient will have far less trouble working under medical supervision with proper treatment in the factory than working elsewhere. Only twelve cases in four years have applied for treatment.

Flat Foot.—This is again a much over-rated condition. The number of men having painful or weak feet is small compared to the number having flat arches. In our experience a high arch has more frequently given trouble than a low one. However, flat foot may in some cases be a factor in back strain and for this reason is of interest. We have encountered sixty-seven cases in four years.

Varicocele.—This condition has never given any trouble in our experience.

Hearing.—Deafness, while it increases slightly the general risk of the individual, and makes explanations of work more difficult, is no bar to employment except in special departments. Many foremen at Norton Company prefer men who are deaf as they attend to business.

Vision.—As already stated, there is a distinct eye hazard in the abrasive industry and men with badly defective vision should not be employed. This, however, is not to be construed as applying to other types of industry.

Arteriosclerosis.—The importance of this defect depends on its etiology and the accompanying changes in other organs. At Norton Company during the past four years there have occurred two cases of cerebral hemorrhage among workers. Arterioscle-

rosis without abnormally high blood pressure probably causes no trouble unless of syphilitic origin; that is, under medical supervision these cases are able to do good work for years without undue absenteeism because of sickness.

Endocarditis.—In the great majority of cases, endocarditis, except when compensation is lost, is no bar to employment. Returning to the author's clinic, in 1920 the employees numbered approximately four thousand. The number of possibly defective hearts, that is, hearts having a definite murmur, probably organic, under study was 118. Of these ten lost time because of heart trouble. During 1918 and 1919 the total number of cases of heart trouble, applying at shop clinic for advice other than when sent for, was ten. During the same years fourteen lost time because of heart conditions. During the four-year period 1916 to 1919, ninety-two men applied for treatment giving "heart" as the reason. During the same period 14,502 applied for treatment because of respiratory disease. The functional power of the heart muscle for work should be the deciding factor and this can be rapidly and fairly well determined by simple tests.

Tuberculosis.—Active tuberculosis has, of course, no place in the factory. Its presence should bar employment. When it appears among members of the working force, it should be isolated and the worker sent to a sanatorium. Here, again, the number of cases in the author's experience is small. During the year 1920, three applicants were rejected for tuberculosis and five cases were discovered among the employees, the force then numbering four thousand. Chronic bronchitis, emphysema and asthma may or may not cause trouble depending on the type of work available. At Norton Company they are a poor risk in many departments because of the dusty nature of the business. Fifty-nine cases applied for treatment in four years.

We have now considered all the conditions listed by the Conference Board as sub-standard and note that on the whole they do not present a very large number of cases. The time loss occasioned by these defective conditions is interesting. In 1920 this was as follows:

	No. of Cases Applying for Treat.	Days Lost
Hernia (developing during work)	8	201
Hernia (preexisting) . .	0	None
Varicose Veins	0	None

	No. of Cases Applying for Treat	Days Lost
Flat Foot	15	125
Varicocele	0	None
Deafness	0	None
Vision	0	None
Arteriosclerosis	0	None
Heart	10	241
Tuberculosis	5	136

Excluding the hernia cases, in none of which the hernia was present on admission, we find the total number of defects which caused loss of time was thirty and the number of days lost 502. This appears small as compared with the time lost from sickness, which was 11,648 days for the same period.

There are three partly preventable conditions which caused the loss of considerable time. These are:

	No. of Cases	Days Lost
Back Strain	22	335
Rheumatism	34	348
Tonsillitis	46	328
	102	1,011

Back strain is important because of its frequency and the large number of cases in which there is arthritis of the spine. In the presence of arthritis a very slight strain produces rather severe disability.

Rheumatism is frequently present when the worker is hired and is not detected until he comes to the shop dispensary complaining of pain. A physical examination which does not include the joints has little value in properly placing and guarding rheumatic cases. Rheumatic cases also constitute a risk from the point of view of injury.

Tonsillitis causes a considerable time loss, is distinctly contagious, besides being a precursor of focal infection. We should at least review all cases with suspicious throats more frequently than we do and be more firm in advocating tonsillectomy. Mock in his "Industrial Medicine and Surgery" calls attention to the fact that twenty-eight employees paid 160 visits to the doctor's office and remained home seventy-one times chiefly on account of tonsillitis and allied conditions prior to tonsillectomy. The same group made sixty-eight visits to the doctor's office and were absent from work only thirty-three times following tonsillectomy, an improvement of approximately 50 per cent.

After reviewing past experience, using the author's clinic as a basis, the following conclusions seem warranted:

(1) Applicants having the following defects may be admitted to most factories without undue risk, provided they are selectively placed and watched.

(a) Hernia of long duration which is complete or well held by a truss provided the applicant has done work similar to that for which he is hired for the four weeks preceding.

(b) Varicose veins, provided ulcer and edema of ankles are absent.

(c) Varicocele supported by suspension.

(d) Flat foot if without symptoms, that is pain in foot when applicant walks on toes. Pain in back on bending over.

(e) Deafness, except in special departments.

(f) Vision, depending on hazard and department.

(g) Arteriosclerosis.

(h) Endocarditis, unaccompanied by marked myocarditis.

(i) Arrested tuberculosis—in special departments.

Special search should be made for the detection of:

(1) Arthritis of spine or sacroiliac region.

(2) Arthritis of joints of long bones.

(3) Old injury to bones entering into a joint.

(4) Infected tonsils and those suggesting tendency to infection.

(5) Potential hernia in southern Europeans of the stocky build who have protruding abdomens and have not been doing heavy work for three or more weeks preceding hiring. These men present a rather relaxed external ring and there is slight bulging along the inguinal canal on cough.

From our experience we consider these five types of defect specially hazardous. They seem to figure largely in all industrial disability records.

Nurses in the Guise of Industrial Physicians

The Nurse's Whole Authority Is the Physician's Order; Nursing Care Is Not Medical Service

By WILLIAM ALFRED SAWYER, M.D., EASTMAN KODAK COMPANY, ROCHESTER, N. Y.

ABOUT a month ago I received from a physician, unknown to me, the following letter:

I see that you are to read a paper before the American Association of Industrial Physicians and Surgeons in Boston, on "Nurses in the Guise of Industrial Physicians." As I have been visiting many plants and stores, perhaps I can give you some information on the subject.

Recently I have visited places where formerly a physician had charge of the medical work and now a trained nurse is in charge. In a certain city there is a doctor who trains nurses to do industrial work, even teaching them how to give a physical examination. At the factory where I formerly had charge of all the medical work, the superintendent hired a trained nurse to do the work when I left. The reason given was that nurses can be hired very much cheaper than any doctor.

If physicians do not watch out, nurses will supersede them in medical work in industrial plants, for more and more concerns are getting rid of their doctors. "What can be done about it?"

There is a real dilemma apparent in this phase of the industrial crisis. Fearful for the status of industrial medicine, one group of critics tells us of nurses disguised as physicians who were about to occupy the field, while a "rosier spectacle" contingent offers equally extravagant praise for achievements made, and for work projected. While all this discussion pro and con is going on some of us are more than dubious as to the future of industrial medicine.

For our present consideration employers may be grouped into two general classes: (1) Those who are doing the least possible to protect

Laws did not create the need of medical service to industry. Neither does obeying the letter of the law meet its requirements. Its limitations are set, not by penny-wise and pound-foolish employers, but by industrial physicians themselves.

Here as elsewhere failure follows a low estimate of the problem. No specialist is confronted with greater complexities of a medical nature than those of the industrial physician.

The science of industrial medicine is yet to evolve, but it is in process, and the future is to the honest-to-goodness worker who neglects none of his tasks and delegates none of his responsibilities.

themselves under the law. The large majority of these are those hard-headed men of finance who are "producers," not for the sake of the "game," which, of course, includes the "score," but whose mental processes have but one track,—profits. Of course this results in a medical department conducted on the "half-a-loaf" idea. (2) The class which, in spite of the present depression is growing steadily, those big men of vision and broad mind who maintain maximum standards because the best is such a little way ahead and because they find zest in the chase.

In either of these groups, though

more often in the first, there may be found nurses doing more than is warranted. Aside from the statements in the letter just quoted, many instances might be cited of nurses who are performing certain functions not ordinarily allotted to a nurse, and this may be justified up to a certain limit. If a medical department in industry is to care for all emergency illnesses, it is necessary in the present stage of evolution, that a nurse care for such proportion of these cases as standing orders and constant supervision will justify. Every cold, headache, and digestive disturbance is preferably seen by a physician. In some organizations that is the rule, but it is rare that physicians are proportionately numerous enough properly to consider every case in this way. We are obviously short sighted if in turning over the superfluity of cases to the nurse we feel satisfied that this local, or at best, superficial alleviation, is getting industrial medicine very far along the road to its maximum usefulness. The preventive phase of industrial medicine must be kept in the foreground by never ending instruction in personal hygiene through the employees' individual contact with nurses and doctors, singly and in groups, through the plant paper and other available agencies. We cannot afford to forget that we are identified as a class, whether we wish it or not. What industrial medicine is to become depends upon the efforts and collective personality as industrial physicians. A preacher, notable for his oratory, but of doubtful reputation, was on one occasion told by a parishioner:

"Your character speaks so loudly I cannot hear what you preach." The character of a medical department depends upon the purpose for which it was instituted and upon the personality of the medical director.

The dispensing of medicine by a nurse, for headaches, colds, etc., is allowed in some medical departments. Please note that I said "dispensing," not "prescribing." I consider that if the doctor in charge prepares signed orders regarding such emergencies as a nurse may safely care for, he has done the prescribing in blanket form and all the nurse does is to carry out his orders. That is all any nurse is qualified to do—*carry out the orders* of the physician in charge, thereby safeguarding herself and the department, as well as the employee. If these orders include the taking of temperature and pulse, inspecting the throat, and asking questions regarding elimination and abdominal pain, evidence will be elicited which will serve to indicate when the physician's personal attention is called for.

If the nurse is alert, well coached, and really interested in her job, she will sense real trouble when it presents itself and turn the employee over to the physician.

When the expedient of such blanket orders seems unavoidable, the procedure outlined is about as safe as can be suggested, particularly so if the dispensing of simple and harmless medication is made the occasion of a talk with the patient about personal hygiene and draws out pertinent facts or gives useful information about proper elimination, copious water drinking, abstinence from sweets, eating wisely and only at meal times, sufficient sleep, abundant fresh air, and daily exercise. The ideal to be sought is a staff of nurses so well schooled that, while trying to relieve present emergencies, they will preach and talk in terms not over the heads of employees, the gospel of prevention.

There may be those who object to this practice on the part of the nurse of dispensing medication, on the basis that employees usually come to the nurse with their ailments self-diagnosed and all the nurse usually does is to give them something for this or that symptom, while neglecting the cause. In practice, however, when an employee states that he feels "all in," the nurse will usually take his temperature and make a pulse reading and send the patient to the doctor, even when she would not hesitate to give a few tablets for a self-diagnosed and often seemingly self-evident condition. The fact remains, however,

that such practice often carries an employee through the day.

This is accomplished as much by the psychology of the situation as by the actual treatment,—a fact not to be overlooked. Neither is the fact to be disregarded that the average person easily hypnotizes himself into a sort of fatalistic disregard of consequences in the future, seeking only to alleviate immediate discomfort, rather than sparing the time and consideration necessary to understand and eliminate the cause. This is directly due not so much to self-diagnosis or medication by nurses, as to the erstwhile habit of the family doctor of riding behind the team of medicine and mystery. Better education, not only of the public but of physicians themselves, is doing away with these "faith pills." To countenance the treatment by a nurse of any physical malady, with its probable complications, could mean no progress or success and could not consistently be tolerated either by the employee or the wise employer.

We have had physicians criticize us for allowing nurses to give medication for colds and touch-up sore throats. I recall a case where the employee reported to a doctor, who was afterward called in, that the nurse at the factory had painted her throat with iodine, whereupon the physician expostulated upon the dangers of iodine used in this manner and ended by saying: "That is just the sort of treatment you can expect from those factory doctors and nurses." In the case cited the so-called "iodine" used was 25 per cent argyrol, which, naturally, the employee mistook for iodine.

What of removing splinters, foreign bodies from the eyes, the opening of small abscesses, treating boils, etc.? Some nurses can cleanse wounds satisfactorily and suture small lacerations. There are nurses, so well equipped by nature, training, and interest, who can be taught to do anything satisfactorily, and thus save much time of higher salaried physicians. This work, to be done with the minimum risk to the patient, certainly needs to be supervised by a physician. Methods and treatments are changing, and it requires association with those active in the profession and study of its literature in order to keep the medical department abreast of the times. Nurses are helping more and more in routine work; they are being taught to put on plaster casts, to take radiographs, to make various laboratory tests and examinations. As a roentgenologist recently

said, "Yes, we can teach nurses to do it all, so that we will have nothing to do but sit in an armchair and give orders."

Worthy of His Hire

It is true that in industry we permit and even expect nurses to do more than they do in private practice. In some instances this has been carried too far and the nurse has done practically everything except care for the graver emergencies. Perhaps the explanation is that the nurse is as good as the doctor. Perhaps one reason why nurses are supplanting physicians in some concerns is that an average nurse can do the bulk of the work the managements want done quite as well as the type of doctor they are willing to hire.

There is a middle ground in what a nurse may do, which on the one hand avoids the dangers of over-reaching her proper function and, on the other, takes reasonable care of the needs of an emergent situation. Certainly, in a concern where no physician is in charge, a nurse should do nothing but give advice regarding personal hygiene.

It is safe to say that only a very small percentage of employers have been adequately impressed with the value of first-class health supervision of employees. Who is responsible for this? It seems to me that the answer lies within ourselves. The management knows that there are certain legal requirements that must be met and, generally speaking, it recognizes that a healthy working force is to be desired; but there are so many problems of labor with which management has had to deal, that such a thing as real industrial hygiene or medicine is to them only a thing of theory to be taken up some time in the future.

There is still another phase to this subject. At the beginning of the present business depression a number of industries curtailed their medical work to the extent of dismissing some of their physicians, and often without the customary notice. In one case, of which I have personal knowledge, several full time physicians were dismissed without any warning whatever,—as unfair a thing as one could imagine. I am not questioning the need of such action, but simply the result. In this particular instance it was a genuine tragedy. Some of these men who were in middle life, with families, licensed to practise in only a limited number of states, were left high and dry without a moment's notice. All other workers connected with industries can go into any state

and accept various positions without any state regulations, but not so with the doctor. He can practise only in those states in which he is licensed; hence the pinch of an unexpected release. Many will say: "Well, if doctors are going to enter industry, they must expect to meet the exigencies they encounter." Surely, they must, but "if they enter" looms large in view of what has happened during the present period of depression, and which, of course, may happen again. Can we urge the young graduate to enter the field as a specialty for his life work? The present outlook would make one hesitate to do so, and to one who believes thoroughly in full time physicians in industrial plants, this is a situation for thought.

Doesn't this all resolve itself into a question as to the ultimate opportunities for the physician entering industrial medicine? How far will he get professionally and financially? Not so long ago I heard one of our very able members remark that he was seriously considering the resumption of private practice, giving as his reason the apparent limitations of industrial work financially: five thousand dollars, six thousand dollars—a possible ten thousand dollars—is not a very adequate return for real ability and service nor a high objective to have for a family income, especially when so often the years of preparation and apprenticeship are long and lean. The nurse in the guise of physician is a flower of short bloom, certainly not to be regarded seriously as supplanting the doctor, and the day will come when the physician in industry will be rated as indispensable, of first rank among the executives, and as important to the organization as the legal counsel.

We are only on the verge of discovering our possible service to industry and we may be sure that the doctor's importance will become apparent as he grasps and feels the situation. With such function he should be worth a real salary to a corporation, but certainly he will not be if the bandaging of injured parts and the giving of pills is all that the physician with an industrial job is interested in, or if he interests himself only in activities where a nurse can be considered as able to supplant him. Even though at the present time often underpaid and unappreciated, good service pressed down and running over, not only of the individual plant doctor, but supplemented by the service of the National Organization as well, will prove the case and make a place which no nurse can supplant.

Industrial Accident Boards Meet

THE eighth annual conference of the International Association of Industrial Accident Boards and Commissions met in Chicago September 19 to 23. The papers and discussions were by representative men in the field and the program touched upon the most vital current questions relating to compensation, legislation, and administration. The developmental background of the present scheme for compensation is reflected in many of the anomalies of its administration, but as it becomes less and less necessary to offer arguments for the principle of compensation, more and more the successive conferences of the International Association seek to solve these difficulties by bringing into open discussion specific problems arising of the administration of the laws.

California, experiencing difficulty in distinguishing between temporary and permanent disabilities, elicited in debate the criteria of differentiation in Colorado, New York, Wisconsin, and Ohio. Minnesota, being on the verge of changing her system of awards, the whole group was concerned in learning what rulings have been found inadequate and what better plans are incorporated in the new.

The Ontario survey to determine percentages of pension cases who have accepted impecunious poverty and the process there looking toward the development of a rate schedule were of current value to all administrative boards. If 40 per cent of the compensation in one district is paid for permanent partial disability, why is this proportion so much more or less in other communities? If Alabama is framing a new procedure, how may she avoid the pitfalls that have hampered other boards? The chief burden of the discussions on administrative problems was the concerted move to develop uniformity in dealing with schedules and the achievement of a legislative wisdom out of their experience to supplement expert judgment on the merits of the individual cases handled.

All of this has to do with cases as claimants for awards. Once disposed of, a case is easily classified, and a sufficient mass of precedent data constitutes a proper basis for future decision. The case that comes up for adjudication, however, is always an open question. Necessarily the administration of the law is in lay hands, while the merits of the case hinge upon highly technical matters.

If successful administration is to be achieved it will be through the clear statement by industrial boards in open meeting of specific problems and their discussion by qualified physicians in terms the layman can understand.

The medical program presented a valuable series of papers on subjects which present the most baffling conditions: "X-ray Interpretations and Standardization," by Dr. Hollis E. Potter; "Concussion and Contusion of the Brain with Post-Concussional Conditions," by Dr. Samuel C. Plummer; "Neuroses—Their Handling from an Industrial Commission Standpoint," by Dr. Lewis J. Pollock; "Can Breaking of Compensation in the Heart be Attributed to Accident?" by Dr. William H. Holmes; and "Medical Aspect of Women's Ills in Industry," by Dr. Clara Seippel.

Especially valuable was the talk of Dr. Plummer on brain injury and the physical methods of differential diagnosis.

Because the term neurosis is so seldom understood by laymen, Dr. Pollock preferred to classify under the definite term "traumatic hysteria," the rather large group of neuroses which simulate so closely the conditions of organic disease. Dr. Pollock outlined the incriminating adventitious symptoms which reveal the fact that traumatic hysteria presents a problem in conduct. In every case there is some form of precedent dissatisfaction as the initial cause of the nervous disorganization.

Dr. Holmes' argument was that, in the absence of external evidence of trauma, the breaking of cardiac compensation must be charged to antecedent disease and not to trauma. In discussing this paper, Dr. Harry E. Mock argued for preventive measures in keeping heart cases from hazardous employment.

Dr. Clara Seippel brought out the fact that as data are not kept on previous health conditions, especially as affecting women workers, which necessitates special efforts to make hygienic conditions right in factories where numbers of female workers are employed. The discussion brought out the limitations in weights women may lift and the heightened susceptibility of women to certain industrial poisons. There is a dearth of records pertaining to the health of women workers as such, said Dr. Seippel. It might be suggested that analysis of compensation cases in which women have appeared would be profitable. S. P. M.

The Transportation of the Injured

By R. R. SAYERS, M.D., CHIEF SURGEON, UNITED STATES BUREAU OF MINES; PASSED ASSISTANT SURGEON, UNITED STATES PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

DURING the past few years the important problem of transportation of the injured has gone through some marked changes. These changes are due in the main to the same things that have revolutionized transportation in other lines—the telephone and motor vehicles, the latter being especially important. Lieutenant Colonel F. S. Breton, of the British Royal Medical Corps, has described in a very interesting manner, in his book, "The Great War and the Royal Army Medical Corps," the effect of these changes.

As to the mining industry, an example might be taken from the old prospectors who twenty years ago lived in a cabin in the Crow Foot Mountains of Montana about twenty miles from the nearest town. If one of them was injured, his pardner cared for him as best he could for several days; then, when it became

brought to my attention. A man working 2,500 feet below the surface in the North Star mine, Grass Valley, Calif., dropped a piece of timber and broke his ankle. He hopped on one leg to a nearby telephone, called up the station tender and told him what had happened. The skip used for hoisting men was lowered and the injured man taken to the surface. A motor ambulance and surgeon had been summoned from the hospital one mile away by use of telephone and were waiting at the collar of the shaft. In just thirty-five minutes from the time the man was injured, he was in the hospital, his broken ankle being Roentgen rayed, after having been set and placed in a plaster cast.

The problem of underground transportation of injured men is usually very much involved. This can best be illustrated by considering the work-

many of which are accessible only through steep, narrow openings. On the Calumet and Hecla Copper Company's property in Michigan, are located the deepest shafts in the United States. The workings of the lead and silver mines of the Coeur d'Alene region of Idaho are deep and extensive, as are those of the copper mines of Arizona and New Mexico and the gold mines of California. The statements made up to the present time have been of conditions in the metal mines of this country and bring out the importance and difficulties of transportation of the injured in such mines. While the coal mines of the United States are not so deep as the metal mines, their workings may be as extensive or even more so.

A Hypothetical Case

To illustrate the transportation problem and at the same time show conditions in coal mines, let us follow a miner from his home to his work and suppose that he is injured in order that we may further show the care he receives. The home of the miner may be a fairly good home with sanitary surroundings, a home that shows it to be cared for both inside and out. The miner leaves his home and walks to the mine carrying his lunch with him, and enters the mine, and this entrance to the mine is well constructed of concrete. He walks down a manway to the working place or room and examines the roof, by tapping it with a pick handle to see if it is safe. There are no props to support this roof or to prevent loose rocks from falling. The miner, although he realizes the roof is not entirely safe, decides to risk it and goes to work mining with a pick. The roof falls and the miner is partly buried by the rock and coal from the roof. This accident is not an actual case but is one prepared to illustrate what might and often does happen. As it is a hypothetical case, we may suppose his injuries to be anything we wish. Let us consider that this man has a

How an improvised stretcher can be instantly made.

necessary to transport him to a physician, this probably was done on an Indian travois made by cutting two poles fifteen or sixteen feet long, laying them side by side, and connecting them by two crossbars, one six feet from the end and the other six feet farther back. The bars were fastened to the poles with nails, bolts, or tied in place with cords. Between the crosspieces lacings of ropes or a blanket were fastened for a litter. One end was then attached to a horse by the saddle girths similar to shafts; the other end dragged on the ground. Two days were required for the trip, as it was very tedious.

Relief Is Speeded

Today if a prospector's partner is injured or sick, the prospector telephones to a physician who motors out and gives the patient attention within a less number of hours than it took days formerly. Further, if hospital treatment is advisable, a motor ambulance is sent out and the patient transferred to the hospital within a minimum length of time. Another example of the effect of the telephone and motor vehicle was recently

ings of some of the larger mining properties in the United States. For instance, the Homestake Mining Company of Lead, S. D., has five shafts varying in depth from eight hundred to twenty-two hundred feet and has more than sixty miles of underground workings, all of which are connected. The North Butte mine at Butte, Mont., is over 3,600 feet deep, and the Leonard, Tramway, Anaconda, Never-sweat, and any of the other twenty odd mines of the Anaconda Copper Company on Butte Hill are all from one to three thousand feet in depth, with miles of extensive workings, many of which are connected, and

Old methods of transportation included the Indian travois, a slow and tedious method of transportation.

As the problem of underground transportation is usually very much involved, difficulties are devised to duplicate the possible conditions to be met.

lacerated wound on the thigh with arterial hemorrhage and is unconscious.

How to Proceed

Now, miners usually work in pairs, so we will consider that the injured miner is found by his partner, who immediately removes the coal and rock from the injured man, examines him, and applies a tourniquet over the artery on the point of pressure between the wound and the heart to stop the hemorrhage. He also applies a first aid dressing to the wound. His next duty is to get the injured man to a place of safety, as more rock and coal may fall. If he is in a low seam of coal, he will use the one-man drag carry. This may be done by tying the injured man's wrists together or by using a loop of cloth or belt passed around the shoulders of the patient and over the carrier's neck; then by crawling, he drags the injured man to a place of safety. The bearer has had to decide why, when, how, and where to transport his patient. His reason for transportation was to get his patient to safety and to the doctor; "when," in this case, was immediately after stopping the arterial hemorrhage; and "how" was determined for him by the low roof, as in a three-foot seam; "where," only until he was sure of safety, which may have been a few feet or many. As soon as he has reached the entry or manway where he can stand upright, he may use "across the shoulders" or "fireman's carry"; this will probably be the method of transportation chosen, as his patient is unconscious and the method is less tiresome to the bearer than many others. This method of carry has been shown in almost all moving picture houses

as a method used by the soldiers in the World War. If the patient becomes conscious, he will object to the use of this method, as the blood flows to his head, and the bearer will use either pickaback or carry in arms. The carry in arms method is very useful in injuries to the feet and legs, but is more tiresome for the bearer than either of the other methods.

If a second man is available, a two-three-, or four-handed seat may be formed. If either the two or three handed seat is used, the free hand may be used to support the injured patient or the injured extremity.

The above methods of carrying an injured man are only suggested for use where more help is not available.

When the patient has been placed

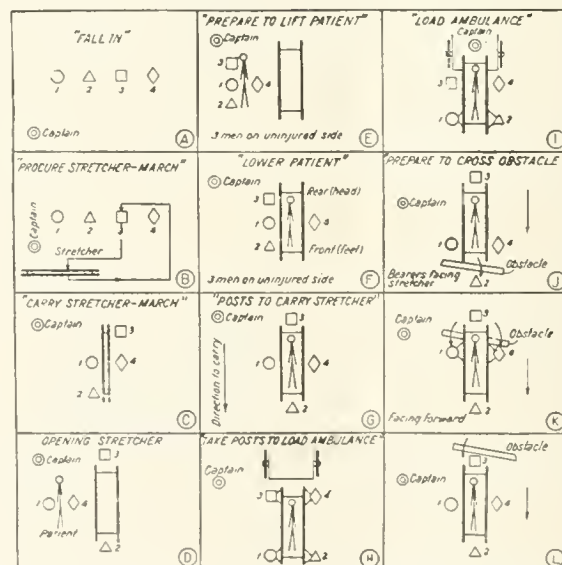

where he is safe and fairly comfortable, it is advisable to secure ample assistance and materials rather than to try to carry him alone or with the assistance of only one other man.

Improvised Methods

Stretchers are almost indispensable in the transportation of injured men. If we suppose that our man is in a coal mine, an army stretcher, or litter as it is sometimes called, will probably be available. This consists of two long poles with a bed of canvas and the poles held apart by hinged iron bars; or a stretcher similar to the army type may be improvised by using two drill steels or poles seven and one-half by eight feet long and a blanket or piece of canvas the same length. After spreading the blanket out, place one pole about one foot from the center, fold the short side over the pole and place the second pole on the two thicknesses about two feet from the first pole; then fold the remaining part of the blanket over the second pole towards the first. When the injured person is placed on the stretcher, the folds of the blanket or canvas are locked by friction.

Another very satisfactory improvised stretcher can be made by using poles similar to those described above and two or three coats or jumpers. The sleeves are turned inside out and the two poles passed through them; the flaps are then turned down around the poles and buttoned underneath.

Had our patient had an injury to the back, a dislocated hip, or a fractured pelvis, a special improvised stretcher splint would have been used.

Stipulated problems, properly supervised, give the men the necessary experience which enables the expeditious handling of the injured.

This consists of two long boards 4 inches by 1 inch by 8 feet, and three short ones 4 inches by 1 inch by 18 inches. The long ones should be placed parallel to each other about four inches apart and the three short ones leashed to the long ones at a level with the patient's shoulders, hips, and ankles. After padding the two long splints, the patient may be secured to the splint by cravat bandages about the extremities and body. This stretcher is very useful in bringing injured men down vertical or steeply inclined manways.

If our miner had been injured in a metal mine, the Stokes navy stretcher or the Homestake stretcher would probably have been used. The Stokes stretcher is a wire woven basket made to fit a man's form and is equipped with straps to secure the patient in the stretcher. He may then be raised or lowered in a vertical position without injury. The Homestake stretcher is made of a solid plank about seven feet long and 1 inch thick and cut to correspond somewhat to the human form. It has a footboard on which the patient may stand when being raised or lowered. Of course he must be securely strapped to the stretcher before transportation is undertaken.

Stretcher Drill Useful

The stretcher drill recommended by the United States Bureau of mines is practically the same as that used in the United States army, the American Red Cross and other military and allied organizations. It is well to study the diagram of the drill shown, as it shows the various duties of each man much better than can be described by words. There are four

Metal mines of the United States present the greatest difficulties of transportation. Coal mines, while not so deep, are even more extensive in their workings.

men, bearers, in the squad, and the captain.

The men face so that the patient will be carried feet foremost. This is the proper way to carry the patient except when going up stairs or up hill, when he should be carried head foremost.

The Use of Masks

If we had supposed the miner to have been injured during a mine fire or explosion from which poisonous gases were produced as sometimes happens, it might have been necessary for the stretcher squad and captain to wear self-contained oxygen breathing apparatus in order to rescue the injured man. They would carry extra oxygen breathing apparatus to be placed upon the injured man to protect him from the poisonous gases. This method has been used at many mine disasters and has

been the means of saving lives which would otherwise have been lost.

While carrying an injured man on a stretcher is a good method of transportation, any carry becomes tiresome if the distance is a few thousand feet, as often is the case in mines. Further the injured man suffers much due to missteps, caused by the rough roadway and poor lighting found underground. To avoid the above objections some mines are equipped with ambulance cars for transporting injured men, when underground. An example of this is found at the Seneca mine of the Calumet & Hecla Co. This ambulance car is nicely upholstered and equipped with springs.

Another type used by the Homestake Mining Company of Lead, S. D., is similar to a two wheel cart, is pulled by hand and not intended to run on the car tracks. It is equipped with springs and covered. In some cases it may be necessary to take the man out where water, dirt or small rock might fall on him. The cover is some protection from these.

An Improvised Ambulance

A practical method of improvising an underground mine ambulance is to equip an ordinary mine car, used regularly for hauling the coal out of the mine, with four springs. The springs are attached to the upper edge of the sides of car near the corners and the stretcher suspended in the car from these springs. This method can be used in most of our coal mines. The springs should be placed with the stretcher so that both may be obtained at the same time.

To summarize: The reasons for transportation are to get the injured man to a place of greater safety, to make him more comfortable, to prevent further injury through handling,

A practical method of improving an ordinary mine car with springs for the comfortable transportation of the injured.

The Seneca Mine of the Calumet & Hecla Co., furnishes an ambulance car, upholstered, and equipped with springs, for the transportation of its injured.

and finally to get him where he may receive proper treatment.

How to transport, or the method of transportation, may be one-man, two-man, stretcher squad, or car transportation—any one or all of which may be used for one or more injured persons.

When to transport an injured person will depend upon the nature of the injury—for he often must receive proper first-aid or emergency treat-

ment prior to transportation—whether the present location of the patient is safe or not, and the availability of assistance for transportation, and the availability of capable and efficient equipment and personnel for treatment.

Maryland Health Demonstration

Washington County has been suggested by Dr. John S. Fulton, Baltimore, secretary of the State Board of Health, as the section for the demonstration in efficient health administration about to be launched under the auspices of the State Department of Health, the United States Public Health Service, the School of Hygiene and Public Health, and the International Health Board. Dr. Richard P. Normant, Hagerstown, will be in charge of the field work.

The Stokes Navy Stretcher is a wire woven basket made to fit a man's form and fitted with straps to secure the patient so that he may be raised or lowered in a vertical position without injury.

A Study of Industrial Absenteeism

The Problem Is Half Solved When It Is Understood and Fully Stated

By ROBERT S. QUINBY, M.D., SERVICE MANAGER, HOOD RUBBER COMPANY, WATERTOWN, MASS.

THE lack of convincing information concerning industrial absenteeism is the most conspicuous feature in connection with this subject. There has been, to date, very little available knowledge either as to the amount of time lost by employees of industry, the reasons for this loss, or methods for minimizing it. The economic loss to industry and its participants on account of absenteeism has never been fully appreciated. Some general surveys have been made, but they have usually covered only brief periods of study, unusual groups of employees, or questionable methods of collecting data which has had a tendency to discount many of the conclusions drawn from the studies. Most of the studies of conditions in foreign countries have been based on health insurance conclusion, and the data presented in the reports has not always been convincing to an impartial observer.

It has been the purpose in making the investigation on which this study is based to collect sufficiently correct and adequate data so as fairly to represent the facts as they exist among this group of industrial workers. It is also the object to make these facts available in such form as to stimulate

further research, and particularly for comparison with other groups, so that some definite and reliable conclusions may be reached and some constructive program directed toward the prevention of this form of industrial waste may be instituted.

This investigation has covered twenty-eight months, extending from January 1, 1919, to April 30, 1921. This period has been unusual in several respects; (1) It has represented a time of unusual business conditions, including a rapid expansion, a peak of production followed by a period of gradually increasing business depression, during the latter months of which a considerable reduction has been made in the number of employees. It has included the latter portion of the first influenza epidemic and the entire second year of the epidemic, which again, was complicated by unusual weather conditions. In addition to this abnormal epidemic should be mentioned the numerous and serious sequelae resulting from the primary cases of influenza.

During the twenty-eight months of this study the average number of employees was approximately 6,700, and was composed entirely of factory workers, the clerical force not being included in the statistics herein sub-

mitted. The group was made up of 65 per cent males and 35 per cent females, of which 55 per cent were married, and 45 per cent single.

The following table represents the nationality distribution:

Race	Per Cent
Americans	50
Italians	15
English	7
Irish	7
Armenian	5
Poles, Greeks, Lithuanians, each...	3
All others	7

Age Distribution	Per Cent
Under 20 years of age.....	15
20 to 30 years.....	40
30 to 40 years.....	24
40 to 50 years.....	13
50 to 60 years.....	6
60 years and over.....	2

The residential grouping was as follows: Watertown, 25 per cent; Metropolitan Boston, 24 per cent; Cambridge, 20 per cent; the remaining number came from other cities and towns which compose Greater Boston district.

The length of employment groupings were as follows:

	Per Cent
Employed under 1 year.....	28
1 to 2 years.....	18
2 to 3 years.....	17
3 to 5 years.....	20
5 to 10 years.....	5
Over 10 years.....	12

TABLE I.—ABSENTEEISM BY CAUSES DURING TWENTY-EIGHT MONTHS, JANUARY 1, 1919, TO APRIL 31, 1921.

CAUSE	PER CENT OF WORKING TIME LOST	PER CENT OF ALL TIME LOST
SICKNESS	2.036	37.06
INDUSTRIAL ACCIDENT	0.139	2.52
NON-INDUSTRIAL	0.079	1.44
PERSONAL REASONS	3.840	58.98
TOTAL	5.494	100.

Thirty-eight per cent have no financial dependents.

In considering the fact that the average number employed was approximately 6,700, it should be remembered that a much greater number of individuals was represented during the course of this investigation because of the labor turnover which occurred during this period.

The above facts have been given for the purpose of indicating that the group under investigation is a very representative one from all points of consideration. It should also be kept in mind, as before mentioned, that this study has to date covered a very unusual industrial period from both general employment and health standpoint, and that the natural expectation would be that the facts brought out in this investigation would be less favorable than during a reasonably normal time.

Although it had been our custom to investigate absences prior to January 1, 1919, the information secured was not sufficiently detailed or comprehensive to be included in this report. On January 1, 1919, our Benefit Plan became effective, and it has been necessary for the proper administration of this plan to make detailed and accurate investigations concerning absenteeism, and carefully to record results.

The Benefit Plan provides for financial aid in cases of sickness, non-industrial accident, and death. After a seven-day waiting period, benefits are paid weekly to sickness and to non-industrial accident cases in amounts ranging from eight dollars to twelve dollars, and covering a

period of from seven to fifty-two weeks, depending on length of employment, from three months to five years. In cases of death we also pay benefits ranging from two hundred to one thousand dollars, likewise depending on length of employment, to the dependent beneficiaries.

All absences are reported daily to the central office by various department heads, and on the second day of the absence throughout practically all this investigation, each absentee was visited by a nurse. She determined the reason for absence, the probable length of disability and rendered whatever services were possible or practical in cases of sickness or acci-

dent cases, and on account of fifty-three deaths to employees. More than thirty thousand home visits were made by physicians and nurses within the twenty-eight months. Because of the small number of deaths, no conclusions concerning mortality rates have been included in this report.

Without going into detailed statistics, attention is called to some of the outstanding features connected with our absence experience during these twenty-eight months.

The employees in the group covered by this investigation lost an aggregate of 245,442 days from work during the twenty-eight months of study. When reduced to days-lost-

TABLE III.—ABSENTEEISM DUE TO SICKNESS AND ACCIDENT: BY AGE GROUPS.

AGE GROUPS	DAYS LOST PER EMPLOYEE ON ACCOUNT OF							
	Total Sickness and Accident		Sickness		Ind. Accident		Non-Ind. Acc.

dent. Frequent recourse was made to the diagnosis of the attending physician, as well as to the assistance of our own physician.

All cases of sickness or accident were re-visited or they came to the hospital personally at least once a week during the period of disability; in many instances these cases were followed nearly every day. As time has gone on, we have more carefully checked and investigated reasons for these disabilities and absences, and I believe that during at least the last twenty months of this investigation, the information obtained has been as nearly correct as is possible to collect in any such investigation.

During this period financial benefits were paid to 2,137 sickness and acci-

per-employee-per-year this represents loss of time as follows:

	Days per Employee
Sickness	6.61
Industrial Accident.....	0.45
Non-Industrial Accident....	0.25
Personal Reasons	10.95
Total for all causes.....	18.26

No detailed tabulations concerning days lost on account of personal reasons have been included in this report because of the necessarily high factor of error which is bound to enter into such an investigation. In general our experience has indicated that time lost on account of personal reasons is due to a great number of indefinite causes, and the absenteisms are of short duration, making it almost impossible to obtain accurate causes for the absences.

Table I indicates that the total average lost time from all causes during this period has been 5½ per cent of the working time, of which approximately 2 per cent was lost on account of sickness, 0.14 per cent on account of industrial accidents, and 0.08 per cent because of non-industrial accidents. A study of our experience would indicate that, except in very unusual periods, sickness disabilities should not exceed 2 per cent of the working time, or, in other words, six

TABLE II.—ABSENTEEISM DUE TO SICKNESS AND ACCIDENT: BY SEX AND MARITAL CONDITION.

SEX AND MARITAL CONDITION	DAYS LOST PER EMPLOYEE ON ACCOUNT OF			
	Total Sickness & Accident	Sickness	Industrial Accident	Non-Ind. Accident
Married Males	5.03	4.45	0.42	0.16
Single Males	4.91	4.36	0.32	0.22
Widowed and Divorced Males	5.94	4.85	0.09	0.99
Total Average Males	5.00	4.43	0.37	0.20
Married Females	13.51	13.07	0.11	0.33
Single Females	6.87	6.56	0.13	0.17
Widowed and Divorced Females	12.48	10.47	0.00	2.00
Total Average Females	8.73	8.35	0.12	0.27

Total Single	5.83	5.39	0.24	0.19
Total Widowed and Divorced	9.11	7.59	0.05	1.47
Total Average	6.31	5.79	0.29	0.23

days per employee, based on the three-hundred-day working year.

Variability in Time Loss

Sickness and accident accounted for 41 per cent of the total time lost, while personal reasons were responsible for 59 per cent. It is of interest to note, however, that at times the percentage of sickness and accident disability to the total lost time has varied between the extreme limits of 33 per cent and 66 per cent. These variations have been brought about by both changes in industrial employment demands and varying health conditions. The abnormally high sickness rate during part of this period has had a tendency to increase the percentage of working time lost due to sickness, while employment reductions have had the effect of decreasing personal reasons absenteeism, particularly during the latter months of the investigation.

Table II concerns absenteeism due to sickness and accident by sex and marital conditions and shows some very interesting variations. Single employees lost much less time than married persons, single males less than single females. Married males lost 2 per cent more time than single males, widowed and divorced males 21 per cent more, single females 40 per cent more, widowed and divorced females 154 per cent more, while married females lost 175 per cent more.

It is generally admitted that both married males and females show a lesser labor turnover than single persons, but a portion of this employment stability is sacrificed for the higher absentee rate of these married individuals, and from the standpoint of absenteeism alone, our experience indicates that married and divorced individuals are a considerable liability.

TABLE V.—ABSENTEEISM DUE TO SICKNESS AND ACCIDENT: BY DAYS OF THE WEEK.

NATIONALITY	DAYS LOST PER EMPLOYEE ON ACCOUNT OF							
	Total Sickness and Accident		Sickness		Ind. Accident		Non-Ind. Accident

Russian	3.93	12.31	3.78	11.87	0.11	0.00	0.03	0.43
All Others	3.77	8.40	3.10	8.30	0.11	0.00	0.56	0.09
TOTAL	5.00	8.73	4.43	8.35	0.37	0.12	0.20	0.27

Table III, showing absenteeism by age groups, indicates, first, that male employees lost on account of sickness and accident on an average of five days, whereas female employees lost approximately eight and three-fourths days.

Below the age of forty, the lost time by males is below the average male disability, while beyond the age of 45, males show a rapidly increasing morbidity rate. In the case of females, the rate remains less than the average up to the age of thirty, while beyond that age the rate increases. From an employment standpoint, therefore, we might well give careful consideration to women over the age of thirty, and men over forty.

Racial Factors Enter

According to Table IV, which shows disability by nationalities, the American born tend to lose less time from sickness and accident than most other nationalities. The relatively small number of certain nationality groups here considered, however, tends to discount the reliability of conclusions

drawn over such a short period of time.

Our experience, as shown by Table V, indicates that the male disability rate is higher on Monday than on other days, and gradually decreases until Saturday, when it again takes a slight rise. The female rate likewise is higher on Monday, and decreases until Friday, when it again increases slightly. Changes in wage payment systems, as well as in Saturday workday schedules, have undoubtedly had a varying effect on this condition in our particular case, but it is doubtlessly fair to say that the sickness rate is slightly higher in both sexes on Monday.

An interesting variation in time lost on account of sickness and accident from month to month is shown in Table VI.

During the months of March and April, 1919, the morbidity rate showed a considerable increase above the average, due to a large number of influenza-pneumonia cases. During the months of January, February, March, April, and May of 1920 our experience again indicated an abnormal sickness disability rate due to the second year of the epidemic and to complicating diseases. During the winter of 1921 there was a slight increase in sickness rate which would be attributed to no particular epidemic, but to the natural increase in sickness during the winter months.

High personal reasons absenteeism conforms to what might be expected, namely, increases during the spring and later summer, and during the abnormal weather conditions which prevailed in the latter part of January and the month of February of 1920.

It is interesting to note the rapidly declining personal reasons rate, beginning in the fall of 1920, this

TABLE IV.—ABSENTEEISM DUE TO SICKNESS AND ACCIDENT: BY NATIONALITY.

DAY OF THE WEEK	PER CENT OF EMPLOYEES ABSENT FROM WORK					
	TOTAL		MALE		FEMALE	
	1919	1920	1919	1920	1919	1920
MONDAY	6.34	5.77	5.11	4.66	8.65	7.82
TUESDAY	5.83	5.66	4.70	4.56	7.97	7.67
WEDNESDAY	5.33	5.29	4.29	4.19	7.84	7.33

	1919	1920
AVERAGE PER CENT OF FEMALE ABSENTEES	8.06	7.55
AVERAGE PER CENT OF MALES ABSENTEES	4.52	4.32
DIFFERENCE	3.54	3.23

reduction being attributable to a reduction of the employed force, which, as above mentioned, tended to decrease personal reasons absenteeism.

As a general rule, a chart of disabilities by causes, by months, indicates that the months of high sickness disability also show a high personal reason rate. This is usually due to sickness in the family which necessitates the employee's absence from work.

When studied by months, the rise and fall of disability on account of accident follows fairly well the curve of sickness. This may indicate that the conditions which cause sickness disability also cause accidents, or that employees who are physically ill are more apt to be injured than well employees. In the past there has been a tendency on the part of safety and illuminating engineers to place the responsibility for the winter increase in accident frequency on improper illumination. Our experience would indicate that a study of accident frequency, and disability, and sickness absenteeism, together with the hourly distribution of accidents, might lead to some constructive conclusions.

Table VII shows sickness and accident disability by physical examination classifications. Applicants for work are physically examined prior to employment, as well as being examined periodically during employment, and are classified as follows:

Class 1.—Persons physically fit for any employment, showing no physical defects of consequence.

Class 2.—Persons physically fit for any employment, but showing minor physical defects.

Class 3.—Persons showing subnor-

TABLE VI.—PERCENTAGE OF WORKING TIME LOST, BY MONTHS, JANUARY 1, 1919, TO APRIL 31, 1921.

TABLE VII.—STATISTICS OF ABSENTEEISM DUE TO SICKNESS AND ACCIDENT: BY PHYSICAL EXAMINATION CLASSIFICATION.

PHYSICAL EXAMINATION CLASSIFICATION	DAYS LOST PER EMPLOYEE ON ACCOUNT OF							
	TOTAL SICKNESS & ACCIDENT				NON-IND. ACCIDENT			
	Male	Female	Male	Female	Male	Female	Male	Female
CLASS 1	4.67	7.37	4.25	7.07	0.25	0.09	0.16	0.21
CLASS 2	5.27	10.72	4.51	10.31	0.59	0.11	0.16	0.30
CLASS 3	6.23	11.92	5.59	11.12	0.44	0.80	0.21	0.---

mal conditions due to some grosser physical defects, and only employed in specified occupations.

This table indicates that time lost on account of sickness and accident conforms quite closely to the risk as suggested by the physical examination classification. In considering this table it is to be noted that certain unclassified cases are not included in this table, so that the total lost days does not conform to those in other tables; but, as far as the figures are shown, they indicate conditions as they exist.

During the year 1920, diseases were

classified according to the "International List of Causes of Death." It is difficult, without going into detail, to give comprehensive comparisons according to this classification, so I have first taken the main divisions, and our experience shows that time is lost according to Table VIII.

General diseases—including tuberculosis, rheumatism, influenza, diphtheria, scarlet fever, typhoid, etc.—caused 1.46 days disability per person.

Respiratory diseases—including colds, bronchitis, pneumonia, pleurisy, etc.—caused 1.26 days disability per person.

Diseases of the digestive system caused 1.11 days disability per person.

Ill defined and unclassified sicknesses caused 1.09 days disability per person.

Affections produced by external causes caused .41 days disability per person.

Diseases of the bones and organs of locomotion caused .32 days disability per person.

Diseases of the nervous system and organs of special senses caused .22 days disability per person.

Diseases of the circulatory system caused .16 days disability per person.

Non-venereal diseases of the genito-urinary system caused .15 days disability per person.

Diseases of the skin and cellular tissue caused .09 days disability per person.

The puerperal state caused .05 days disability per person.

TABLE VIII.—ABSENTEEISM DUE TO SICKNESS AND ACCIDENT: BY DIAGNOSIS CLASSIFICATION, 1920.

DIAGNOSIS CLASSIFICATION	DAYS LOST ON ACCOUNT OF					
	TOTAL		MALE		FEMALE	
	Total	Per Employee	Total	Per Employee	Total	Per Employee

Diseases of the Resp.-System	11,561	1.264	6663	1.119	4898	1.534
Diseases of the Digest. "	10,123	1.107	4822	0.810	5301	1.660
Non-venereal Diseases of the Genito-Urinary System	1,378	0.152	310	0.052	1068	0.334
The Puerperal State	528	0.058	----	-----	528	0.165
Diseases of the Skin and Cellular Tissue	792	0.087	536	0.090	256	0.080
Diseases of the Bones and Organs of Locomotion	2,900	0.317	1750	0.294	1150	0.360
Malformation	48	0.005	45	0.008	3	0.001
Affections Produced by External Causes	3,740	0.409	2418	0.406	1322	0.414
Illdefined & Unclassified Dis.	3,462	0.379	1070	0.179	2392	0.749
Sickness of Short Disability	6,609	0.727	3066	0.515	3543	1.010
TOTAL	57,703	6.310	29762	5.000	27941	8.730

Malformations caused .005 days disability per person.

Considered from the viewpoint of individual diseases, the more important follow in order:

Influenza caused .718 days disability per person; colds, .53; tonsillitis, .341; bronchitis, .312.

Pulmonary tuberculosis caused .24 days disability per person.

Rheumatism caused .235 days disability per person.

Appendicitis caused .171 days disability per person.

Broncho- and lobar pneumonias

caused .169 days disability per person.

Pleurisy caused .095 days disability per person, while hernias cause 0.91 days disability per person.

If we combined influenza, pulmonary tuberculosis, broncho- and lobar pneumonia, pleurisy, and other respiratory diseases, our experience in 1920 indicates that this group caused more than 35 per cent of our total disability on account of sickness and accidents combined.

It is interesting to note from Table IX that females lost practically twice as much time on account of influenza,

Percentage of time lost—by months and causes.

colds, and tonsillitis, as males, that the disability from pulmonary tuberculosis, rheumatism, and all types of accident was nearly the same in both sexes, while from broncho- and lobar pneumonia, males lost more than twice as much time as females. The monthly distribution of influenza and pneumonia cases, by sex, indicated that our male employees were disabled with influenza earlier than the females, and that the disability per case was less than with the females. The pneumonia cases, however, showed a longer disability for men than for women.

Detailed experience concerning length of disability on account of sickness and accident is instructive. Our experience on durations of disabilities is:

Duration of Disability	Per Cent of Cases
Less than 1 week.....	27.02
Less than 2 weeks.....	52.37
Less than 3 weeks.....	66.00
Less than 4 weeks.....	74.65
Less than 7 weeks.....	86.80
Less than 13 weeks.....	93.29
Less than 26 weeks.....	98.15

Many such statistical studies as have been presented here are valuable to the particular industrial establishment from which they are collected, but in order to contribute to the general fund of knowledge concerning industrial morbidity and absenteeism, it will be necessary to collect comparable data from many and various industries. It has been constantly in our minds throughout this investigation that we were securing considerable information which would be of value only after a long period of time, much other data that would be useful only because of their negative nature. We have continued, however, with the idea of discovering for ourselves what was useful and necessary, and also of giving to other industries who may desire it the benefit of our experience, both constructive and destructive.

The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents

Experiments in Air-Conditioning the Home*

The Relation of Health to Atmospheric Environment Demands Scientific Air Control

BY EMERY R. HAYHURST, PH.D., M.D., PROFESSOR OF HYGIENE, OHIO STATE UNIVERSITY, AND CONSULTANT, DIVISION OF INDUSTRIAL HYGIENE, OHIO STATE DEPARTMENT OF HEALTH, COLUMBUS, O.

FOR three winters the author has been carrying on experiments in a small way in air-conditioning his residence. This paper concerns the basic findings of the first winter's work, at the end of which time a change of residence was made to a gas-furnaced house, which has permitted more definite control of the heating factor. Other influencing factors of housing, auxiliary heating appliances, etc., have remained practically the same. The two past winters have, however, been much milder, especially in that cold spells have been of briefer duration.

The Problem

The specific problem whose solution was attempted in the experiments to be described was that of determining whether the average size residence could be air-conditioned, especially in regard to maintaining a proper humidity—40 per cent to 50 per cent—comfortable temperature, and healthful atmosphere during the closed-up season of the year and in a manner to be practical and feasible for the small householder.

The Place

The experimenter used his own residence, the south half of a brick "double" house, facing west, located in Columbus, O., toward the outskirts of the northern part of the city and on an elevation about as high as any in the city limits,—estimated at one

The range of temperatures and humidities favorable to man's best performance has been fairly worked out. The problem now is to devise practical means of enabling him to live under these physiological conditions.

He cannot avoid active exercise, blanket himself with warm, stagnant air, and eat ill chosen food without becoming an easy prey to infection.

A general improvement will follow the wide application of the principles of free ventilation and the variation of air conditions which approximate the conditions of life in the open.

hundred feet higher than the central portion of the city. A solid brick wall separated the experimenter's portion of the building from the other portion, which was also occupied as a residence.

The building was covered with the usual type of slate roof. The basement was built of stone and cement, with a concrete floor four feet below the ground level. It was separated by solid masonry from its neighbor and all in one space. The basement was capable of maintaining fairly fixed air conditions, therefore acting as a good insulation to the base of the building.

The first floor consisted of three rooms in linear order from front to rear, space being taken off of the

center rooms of the building on each floor for the halls and stairways. A rather massive type of brick front porch, unenclosed, joined directly under one roof to the neighbor's porch on the north side, and tended somewhat to temper weather conditions. In addition, a small unenclosed rear porch protected the kitchen entrance to some extent. Practically complete insulation was provided on the entire north side by the other half of the building, and a large frame residence from five to ten feet distant protected the south side.

The second floor had much the same arrangement as the first, consisting of three rooms in linear order with hall, stairway and bathroom located on inner side of building.

A large attic, unfinished, except that it was tightly floored over two-thirds of its extent, acted as an insulator to the top of the building.

The total cubic space included in the experimental rooms—living room, dining room and kitchen on the first floor, and study and playroom on the second floor—comprising 7,569 cubic feet. Deducting space occupied with furniture, fireplace and chimney extensions, etc., approximately seven thousand cubic feet was the maximum cubic space directly concerned in the experiments.

Hence, the abode consisted of an ordinary sized residence place (one half of a brick "double"), located in a city residence district, rather closely built up and at a good relative elevation.

The experiments were conducted between January 8 and February 17,

*The full study, with tables, covering the first winter's findings may be found in the Journal of the American Society of Heating and Ventilating Engineers, 1919, xxv, No. 1, pp. 1-14.

1918, which included the continuous extent of severe weather of a rigorous winter. Actual determinations began on January 10 and continued daily with certain exceptions through February 7, when a warmer spell prevailed for about a week, final determinations being completed on February 17, when another cold spell was at hand.

Factors of Influence

(1) *Protection or General Insulation of the House.*—Because of the construction and situation of the building in relation to neighboring structures, it may be stated that it was perhaps a little better protected from weather conditions than the usual residence, although the elevation of this part of the city permitted probably fuller exposure to weather conditions than is ordinarily the case.

(2) *Special Insulation.*—There were no storm-windows nor storm-doors. However, the looser window sashes and the exterior doors were well weather stripped. Walls and ceilings were lathed except on both outer walls, plastered, and papered. Air filtration leaks and losses of heat by conduction through these were, therefore, to be considered controlled in a fairly thorough manner. (Note, however, the chimney openings of three grates and kitchen.) Hence the brick construction with entire north wall free from openings, the opposing half of building being occupied, the tight basement and large, although unfinished, attic produced, withal, an insulation fully in keeping with, but no better than, the average residence. The flooring on the first floor was double, the upper layer being seven-eighths inch oak, on the second floor single, pine, well varnished.

(3) *Rooms used in Experiments.*—Only the three first floor rooms, and the front room and small rear room on the second floor were included in the experiments, since these were the only rooms where it was attempted to maintain a steady comfortable temperature. A small bathroom on the second floor was omitted as well as a bedroom—the latter unheated. All halls and stairways were omitted. When the furnace was going, the general temperature in the basement ranged from 40° to 60° F. A gas-burner under a non-insulated hot-water tank was going continuously in the basement. This, when the furnace was not in operation, was found sufficient to keep the basement temperature up to at least 32° F, even on the coldest and windiest days.

(4) *Heating Methods and Appli-*

ances.—Coal shortage rendered it possible to continue the experiments only the length of time indicated (January 10 to February 17). The furnace, which burned coal, was placed in the center of the basement and had hot-air ducts with fairly good upward slope. It was, by experience, a fairly good heater and in good condition. During the course of the experiments the outdoor cold-air duct was closed and only the basement intake was used. However, considerable inleakage of outdoor air occurred here, as

tween the second and first floors or between the first floor and basement. However, the indoor filtration leaks were of some importance in creating a circulation and recirculation of air between floors.

Gas grates were present in the front room and middle room on the first floor and in the front room on the second floor, and were used frequently. All were flue-ventilated (without dampers) to the exterior by chimneys. The kitchen was provided with a gas stove which was also used considerably as a heating unit. This stove was also flue-vented, without damper, by a 4-inch pipe to a chimney of good draft. The study was provided with a portable gas-stove which was used fairly often in addition to furnace supply and the gas-grate in this room. The playroom was provided with an overhead gasplate-heater of the yellow flame, complete combustion type, which was also used fairly often. During the experiments, all doors to other rooms, halls and to the exterior were kept closed with the exception of the necessary moments of ingress and egress.

(5) *The Number of Occupants* is a feature of some importance in the matter of both heat and humidity production, particularly when several may be gathered in one room for some period of time. Persons in the household consisted of two adults and two small children. Rarely were these present at one time in any one room.

(6) *Primary Sense Impression* was carefully noted as an important index to the general ventilation of each room. It was always determined immediately upon entering a room.

(7) General "Room Comfort" in the matter of temperature or air movements after the experimenter or others had been present for half an hour or more was also noted with each determination.

(8) A set of reliable thermometers (eight in number) was hung in the various rooms on side walls farthest from heating units at a height of about five feet from the floor. All of these thermometers were calibrated against the dry-bulb thermometer used on the sling psychrometer, the calibrations being made at different degrees of temperature in approximately 10° intervals from 50° to 100° F.

(9) *Psychrometric Readings.*—A pocket type sling psychrometer of first class quality and accuracy was used (Fig. 1). Readings were made at about the center of each room and at the same place always. The

The type of pocket sling psychrometer used. Readings were made at about the center of each room, the psychrometer being whirled until both dry bulb and wet bulb readings were constant, then both read.

is usual in the ordinary type of damper control of such ducts. The house circulation, therefore, was (a) from the basement into (b) the furnace jacket, then (c) through the various hot air ducts and registers to (d) the rooms above, with whatever returns there were through (e) door leaks and leakages about gas pipe openings, etc., passing vertically through the floors. There were no return ducts or registers either be-

psychrometer was whirled for a minute or two until both the dry bulb and wet bulb readings were constant, then both were immediately read. Distilled water, which stood in covered glass tumblers in each room, in order to insure "room temperature" of the water used, was used for moistening the wet bulb. Relative humidities were determined by consulting a psychrometric table in the usual manner.

(10) As each indoor psychrometric reading was made, the *outdoor temperature*, as indicated by a standardized thermometer hung on the building wall on the back porch was also read.

(11) *Official Weather Conditions.*—At the completion of the series of experiments, in response to a request made to the Director of the local Columbus Weather Bureau, the experimenter was supplied with a report of the weather conditions in regard to (a) temperature, (b) relative humidity, (c) wind velocity, and (d) wind direction for each of the hours corresponding to the readings made in the home experiments. Only occasionally did the official records as to temperature vary more than two or three degrees from those noted by the back-porch thermometer, in which cases official records were invariably more extreme than those given by the experimenter's thermometer, which was therefore on the safe side. The experimenter did not attempt any psychrometric readings out of doors.

(12) *Temporary Disturbing Factors* consisted principally of laundry work, weekly, in the basement where an additional gas plate heater, under a clothes boiler, and the escape of some steam and moisture from clothing hung up to dry, played a certain small part in improving humidity conditions. In a lesser way, some types of cooking in the kitchen produced some humidity. As, however, but few quarts of water at the most were evaporated by these means, such influences were not of much importance.

(13) To increase air movement an eight-inch electric fan, driven at the medium of its three available speeds, was placed in the basement intake to the furnace and kept running for periods of from two to six hours previous to making readings. As noted by the rush of air out of the registers, this very materially improved the circulation of the air throughout the house. No attempts were made to estimate air velocity, air displacement or air direction in various rooms,—the variations in these factors being, of course, great, but these factors no

different than in all inhabited quarters, where they are necessarily controlled sufficiently to insure more or less comfort.

(14) A *Humidifying Apparatus* was installed in an opening in the slanting portion near the top of the furnace-housing so that the water spray continually played on top of the dome of the firebox within. This device works on the atomizer principle, although in order to get sufficient water into the air with the city water pressure available (14 to 25 pounds), it was often necessary to have the particles of rather larger size, on the average, than could be called "fog." So far as could be seen, this proved no detriment provided evaporation took place, which in turn depended mainly upon the heat in the furnace. Except for certain experimental purposes, the device was kept going for at least a half-day period before readings were made in the rooms above and on some runs was in continuous operation for forty-eight hours at a time. The amount of water supplied by the device was within easy control of the experimenter. In the early experiments it was found that not enough water was being used and hence humidification effects were only slight or nil.

(15) The drying surfaces of the house were those ordinarily present, such as rugs, varnished furniture, clothing, wall paper and varnished woodwork—all of which, as it is well known, have a most remarkable capacity for absorbing moisture, at least in the first few days of artificial humidification attempts. When all of these have reached a condition of moisture saturation in general keeping with that of the air, these factors practically cease to be of importance as atmospheric dehydrating agents.

(16) Auxiliary heating by natural gas appliances was used quite extensively because of the severity of the weather and the shortage of coal, and it early became apparent that the burning of natural gas in a room, in itself, had a marked influence on humidity relations, its use being accompanied by a concurrent rise, invariably, in the humidity readings. Therefore, so far as the efficiency of the humidifying device was concerned, only such readings as were made when a minimum amount of, or no, gas heating accompanied were taken.

It will be seen that the total number of devices used in these air-conditioning experiments in the abode in question (in addition to the building construction with the amounts of insulation and air leakage indicated)

were (1) an ordinary, hot-air furnace, coal heated; (2) gas-grates, gas-stoves, and one overhead gas-heating plate—all burning natural gas; (3) standardized thermometers, one hung in each room; (4) an eight-inch ordinary electric fan placed in the basement opening of the cool-air inlet at the side of the base of the furnace; (5) a humidifying apparatus connected to the water supply; (6) a pan to catch the overflow from the humidifying apparatus; (7) the city water supply, which ranged between 14 and 25 pounds' pressure, as gauged in the basement, and (8) a pocket sling psychrometer with accompanying psychrometric chart and some distilled water (placed in covered tumblers in each room for moistening the wet-bulb thermometer). Other essentials in conducting the experiments were observations as to weather conditions, including official local reports corresponding to the hours when the home readings were made, notations as to the number of persons present, and the presence or absence of temporary disturbing factors.

Experimental Findings

Tables showing the results of the experiments are omitted because of lack of space, but the following summaries give the essential facts of each table:

(A) *Experiments in rooms heated by direct gas-heating appliances (grates, stoves and plates).*—In 24 experimental readings made in comfortable living rooms, the experiments made on 13 different days (between January 10 and February 17) with outdoor temperature ranging from 0° to 38° F. and outdoor relative humidities ranging from 63 per cent to 91 per cent and wind velocities from four to twenty-six miles per hour, it was found that the *relative humidities* within the rooms ranged from 37 per cent to 68 per cent. While this does not constitute an ideal condition (60 per cent relative humidity), it conforms to the conditions which are usually laid down as practical of attainment. It would, therefore, seem that no artificial humidification is needed in rooms thus heated (direct heating by grates, stoves and heating plates burning natural gas in the air of the rooms).

(B) *Experiments with hot-air furnace.*—In ten experimental readings made in "comfortable living rooms" (as regards temperature), made on seven different days—between January 4 and February 4—in which heating was by the ordinary hot-air furnace, with outdoor temperature ranging from -6° to 16° F., outdoor relative humidities from 63 per cent to 87 per cent and wind velocities from two to thirty-two miles per hour, it was found that the indoor relative humidities ranged between 15 per cent and 50 per cent, all but two falling

between 15 per cent and 33 per cent. Hence these experiments bear out the statements made by others that the heating of premises by such indirect methods as the hot-air furnace results in great aridity and shows the necessity for providing for humidification of the heated air.

(C) *Experiments with cool rooms* ($59\frac{1}{2}^{\circ}$ to 35° F.)—In fifteen experimental readings made on eleven different days in rooms whose temperatures ranged between the limits stated and which were miscellaneously heated (hot-air furnace and gas appliances) with outdoor temperatures ranging from -5° to 30° F., outdoor relative humidities between 56 per cent and 95 per cent and wind velocities from four to forty miles per hour, the indoor relative humidities ranged between 30 per cent and 64 per cent, nine falling between 44 per cent and 64 per cent. These experiments simply show that as temperatures decrease below the point of comfort in living rooms there is some compensation in the fact that the relative humidity increases to an amount which may be equivalent to the ideal (60 per cent). The cold, damp atmosphere resulting, however, is not to be advocated.

(D) *Experiments in artificial humidification using hot air furnace.*—In twenty-eight experimental readings made in "comfortable living rooms," the experiments made on 10 different days (between January 13 and February 5) with outdoor temperature ranging from -2° to 24° F. and outdoor relative humidities ranging from 56 per cent to 91 per cent and wind velocities from three to twenty-nine miles per hour, it was found that the relative humidities within the rooms ranged from 29 per cent to 58 per cent (all but seven scattered readings—the lowest of these 29 per cent—falling between 38 per cent and 58 per cent). This is, for practical purposes, the normal condition desired. This experiment, therefore, shows that it is practical, with only the outlay described, to humidify artificially the average size and type of residence and include proper humidity as an element in the "comfortable living rooms."

Observations and Deductions

(1) The "comfortable living room" atmosphere may be defined as one in which there is (1) a barely perceptible circulation of the air, yet without draft; (2) temperature not depressingly high nor uncomfortably low with heat more or less evenly diffused throughout the rooms; (3) a degree of humidity which is neither high enough to be depressing nor low (dry) enough to be irritating, and (4) the absence of obnoxious gases, as those escaping from stoves or grates and, obviously, dust, smoke, or disagreeable odors. We may standardize the principal items in the above, and thus be more certain of a "healthful" as well as a "comfortable" atmos-

phere. The air should move at a velocity of about one foot per second; its movement should be varied in direction; and it need not be over 68° F. temperature, provided the degree of saturation with water vapor amounts to about 40 to 50 per cent.

(2) In air-conditioning buildings such as residences the chief problems to be considered and controlled are as follows:

(a) Movement of the mass of air to overcome stagnation and stratification (indirect heating, as by the hot-air furnace, easily accomplishes this while great improvement can be observed by the added use of the electric fan).

(b) Prevention or control of heat loss from the building through the two chief sources: (a) direct filtration of heated air outward and ingress of cold air into the building (these air changes take place rapidly about doors, windows, baseboards, floors, and especially chimney flue openings) and (b) direct conduction of heat through walls, window panes and floors (these are usually sufficiently insulated against by proper building construction, which includes intervening "dead" air spaces).

(c) Loss of water vapor which may have been added to the air for bringing up the humidity requirements.

It will be seen, therefore, that the question reduces itself practically to one of heat and humidity control, part of which is accomplished by correct building construction and the balance of which may be secured by the usual type of hot air furnace and a humidifying device.

(3) Unless double windows are used and outer walls are efficiently insulated, there will be an accumulation of moisture on the roomside of these otherwise cold surfaces. Surfaces of the interior of rooms must approach in temperature that of the room atmosphere or moisture deposits may occur. In the residence described, window panes, only, became steamed or frosted. Unquestionably, double windows would have avoided this. However, there is no evidence that such condensations upon windows or walls become a hazard to the health of occupants.

(4) It was found that a small electric fan turned on for an hour or so three times a day was sufficient to "get the heat out of the furnace," and along with it any added humidity.

(5) When outside temperatures mount above the freezing point (32° F.), at least in the locality in which these experiments were made, it does not appear that artificial humidification of residential atmosphere is necessary. This means, therefore, that, on the whole, the season making such humidification desirable in this part

of the country is not only briefer than is commonly supposed, but that during the cold season many days occur when the outside temperature is above the freezing point. With the persistence of outside temperature below the freezing point, indirect heating methods such as the hot-air furnace, produce an excessively drying tendency, or "dryingness" of the air which should be corrected, both on account of the damage to furniture and decorations as well as for health reasons.

(6) Heating of rooms by naked (natural) gas flames (grates, stoves, etc.) results in an amount of atmospheric humidity which is apparently sufficient (40 per cent to 60 per cent saturation). It was not determined whether this increased humidity comes from the oxidation of hydrogen in the gas or whether it is any more than would result from the presence of any form of naked fire in the room.

(7) Very few precision instruments are needed to measure the quality of a healthful atmosphere. Some of these the householder may do away with and rely upon "primary sense impression" and "comfortable room temperature" as guides. No doubt a little increased watchfulness, or increase in the acuity of the senses, is necessary and may be cultivated.

(8) The effectiveness of any humidifying device is a very relative matter. Much depends upon the control of the heat-loss and moisture-loss through filtration leaks, direct conduction and evaporation. It is conceivable that in quarters insulated against such losses, any humidifying device, in time, would succeed in completely saturating the atmosphere with moisture. Under these conditions, for example, the moisture which a mouse exhales with each breath would in time humidify to saturation a large auditorium. Hence the question of the efficacy of humidifying devices appears to be: "What will supply enough moisture in a few hours' time to bring about a relative humidity of from 40 per cent to 60 per cent in spite of the chances for losses which exist in the ordinary place of residence?" As the experimenter's observations, which correspond with those of others, are to the effect that it requires from a few to twenty or more gallons of water per day (depending upon the temperature of the air to be heated and its rate of escape from the building) to get enough water vapor into the air, it is obvious that some continuously operating device connected with the water supply of the building is the most practical solution. An atomiz-

ing device can be made to accomplish this.

(9) Observations in a number of experiments bore out the statements of others that when *relative humidity* mounts to from 45 to 60 per cent "room comfort" becomes "O. K.," even when thermometers about the rooms record as low as 60 degrees F. While this indicates that a lower temperature than is customary is comfortable under properly humidified air conditions, it does not mean that any less "heating," i. e., consumption of coal, is taking place, since the heat is simply being used at the furnace to evaporate the moisture which comes in contact with the heated air and the furnace box. It does, however, render the living atmosphere more healthful and comfortable, since it does away with the necessity of excessive heating (70 degrees to 80 degrees F.) in order to feel comfortable on cold days. The cost in fuel is probably about the same.

(10) The apparatus needed to bring about "proper air conditions" by the householder is (1) a hot air furnace of ordinary type and an arrangement for air circulation in the rooms and back to the furnace (this return being accomplished either by registers between floors or by loose door and floor constructions, or by leaving stairway doors ajar); (2) a humidifying device, costing about twenty-five dollars, with from three dollars to five dollars additional cost for its installation, the same to be connected to the hot air furnace; (3) a small portable electric fan, costing about ten dollars—the same one used in the summer season for cooling and ventilation; (4) a couple of thermometers costing about one dollar each; and (5) a hygrometer or psychrometer, costing from four to ten dollars. The cost of the amount of water used is insignificant, while the cost of electricity amounts to a few cents a day at the most (the use of the fan for four to six hours). The time necessary for regulating the humidifier and the fan should be made to correspond with that of tending to the furnace, at which place all three are under control.

(11) For brief cold snaps, a temporary expedient for humidifying the air of the house consists in keeping a section of the basement floor near the furnace wet with a hose. Keep the basement intake to the furnace housing open, close the outdoor intake, turn on the electric fan (placed as before), and force the moistened air throughout the furnace distributing system to the rooms,—the air to be re-

circulated to the basement as above explained.

The usual schemes adopted, such as water pans in the side of the furnace

or attached to radiators, etc., unless actually evaporating many gallons of water per day, are practically worthless as room or household humidifiers.

A Hotel for English Children

THE health and happiness of the home depend upon the efficiency of the mother and upon her fitness to be on constant duty. Where ill health on the part of the mother incapacitates her, the whole family suffers. Most of all, the little child is neglected both to its own hurt and to the further complication of an already difficult situation.

The uncared for children often offer the greatest obstacle in the way of the complete restoration of an ailing mother and are often the most complex problem of the health worker. The same difficulties are continuously before the working mother. It has been repeatedly shown that wage earning on the part of the mothers leads to reduced efficiency and impaired health among the children. Everywhere there is too little provision for the care of such children. Day nurseries do not cover the situation.

In London this phase of child care is partly met by the establishment of Beauchamp Lodge Hotel, where children are amply provided for over periods of days, weeks, or months according to the requirements in the case. They are weighed, measured, and cared for as their cases may de-

At Beauchamp Lodge Hotel for Children in London trained nurses are in charge and the utmost supervision is exercised. The institution is a boon for working mothers or for ailing mothers whose households disintegrate during their physical incapacity.

mand. The work receives added importance from the fact that many of the children come from typical working class families in which the food consumed has been shown by numerous studies to be insufficient to maintain normal growth in little children. Whether ignorance of dietaries lies at the bottom of this condition or whether poverty either from individual or social causes is the basic cause, the result is to be reckoned with in terms of shortened life span, lessened periods of productivity, and lowered vigor and intelligence.

Keystone View Company.

The right kind of food in plenty is the order of the day at Beauchamp Lodge Hotel. Here, as elsewhere, contentment is a by-product of well being.

Minimum Health Standards in Schools*

No More Urgent Problem Now Confronts the Health Worker Than the Hygiene of Schools

BY LOUIS I. HARRIS, M.D., D.P.H., DIRECTOR, BUREAU OF PREVENTABLE DISEASES, DEPARTMENT OF HEALTH, NEW YORK CITY

IT MAY be stated without fear of contradiction that ventilation is the most important factor in relation to the health of workers. Defects of ventilation are the most important single cause of disease in industry. A statement of all that the term "ventilation" comprehends when it is used by an industrial hygienist, will make clear why it is of such great significance. This holds equally true with reference to the school, because it is proper to consider the school as the industrial establishment in which are engaged thousands who are acquiring knowledge and submitting to character development,—and their teachers as well,—and it is the business environment in which a considerable fraction of the lives of pupils and teachers is spent each year.

It is commonly understood that ventilation implies the furnishing of an adequate supply of fresh air to a given room, factory, or other space. The industrial hygienist, however, is not merely concerned that the air which is furnished should be adequate in quantity, but that it be free from contamination both before and after it enters a room, and that dust, bacteria, or the exhalations and emanations of the human body and the gases generated by the burning of gas lights are effectively withdrawn; that the air is of suitable temperature and humidity; that it is kept in motion so as not to stagnate; and that it should not be delivered in such manner as to drive it through a given space or room at a great velocity, thus creating a draft. The air supplied must be distributed to all parts of the room, a matter that is especially important when mechanical ventilation is depended upon.

Natural ventilation through windows or skylights is by far the best. If ventilation is obtained through natural means, that is, by an adequate supply of windows or skylights, it obviously implies that lighting will at the same time also be improved. When, because weather conditions are unfavorable, or structural arrangements are old or defective, or when for a variety of other reasons, it is

The why of school hygiene needs hardly be argued. The how is open to much investigation. Engineers are everywhere working out means of maintaining the optimum conditions and formulating standards of equipment which should constitute the universal minimum requirement.

The chief difficulty, however, is with old equipment which has been "good enough" in the past. Too many schools are still dingy, dirty, and insanitary, and appropriations for maintenance and renewal are far below the actual need. When will the public come to a realization of the physical needs of the public schools?

advisable to depend upon natural ventilation, one must reinforce or replace it by resort to artificial methods of ventilation which depend upon fans to propel air into a room as well as to exhaust or remove contaminated air. Frequently, artificial ventilating devices, even though they may have been installed at very great expense and at considerable trouble, have been found to be defective and impracticable in operation. Even when a mechanical system of ventilation is found necessary, it does not justify failure to open windows at all times when the weather conditions permit.

New Ideas of Ventilation

The latter statement is in direct conflict with the views which have heretofore been held and enforced with reference to this subject, and as the result of which no one has been permitted to open windows while ventilating devices were in operation. Authority for this new view is, however, to be found in the special report made by the Divisional Committee on Heating and Ventilation of the Committee on Welfare of the Advisory Commission, Council of National Defense. This most important report was prepared by some of the foremost engineering authorities in the Country. For the sake of emphasis, and to overcome the harmful effects of wrong teaching which has

been in force hitherto, it is desirable to repeat that the installation of a mechanical system of ventilation in rooms where the natural agencies for ventilation fail or are found insufficient, does not justify the old theory that the opening of windows in such rooms destroys the effectiveness of mechanical ventilation when the latter is in operation. From a hygienist's point of view, quoting the exact words of the report above referred to, "a room cannot possibly have too many windows, nor can they be opened too often or too much when the external weather conditions permit."

The report of the Divisional Committee on Heating and Ventilation of the Council of National Defense, which has already been referred to as an authoritative guide, unfortunately does not make adequate provision for the amount of space to be furnished each occupant of a working place. A minimum of four hundred cubic feet of air space per person should be insisted upon; six hundred cubic feet per person is the optimum. While it is our business to urge and compel children who cough or sneeze to cover up their mouths and noses with their handkerchiefs, we must nevertheless provide an adequate amount of space for each child in a classroom, so that it will be out of range of the discharges from a sneezing or coughing neighbor; this is a necessary measure of protection against contact infection. For this purpose, a minimum of twenty square feet of floor space is necessary for each child in a classroom. In apportioning the above amount of space, it is not intended that one should include in such computation those areas of a room which are not used for seating purposes; the aisles, however, may be included in such computation. For the purpose of adequate ventilation, rooms should be required to have a sufficient amount of window space so as to allow twenty-one square feet of window area for every occupant of the room; such windows, however, should open directly to outdoors. When the area of the window space for each occupant averages less than twenty-one square feet in a given room, it calls for the installation of a mechan-

*Part I of this article was presented in the August issue of the NATION'S HEALTH.

ical method of ventilation to supplement natural ventilation. When a mechanical method of ventilation is necessary, the minimum amount of air space should be not less than six hundred cubic feet of air per person per hour.

If, for example, you have a classroom in which there are forty children, and you have only seven hundred square feet of window area instead of the optimum 840 square feet, then you have a deficiency of 140 square feet of window area in such room. For each square foot of window area that is lacking, one hundred cubic feet of air ought to be supplied for each occupant per hour. In other words, the mechanical ventilating device must compensate for the deficiency of window area in the room by supplying 140 times 100 cubic feet of air for each of the 40 pupils. While the essentials of this calculation concern only the engineer, they are offered in this connection to show that it is not sufficient merely to have an elaborate ventilating device in the room, but that the amount of air which is delivered must be accurately regulated. To be satisfied merely with the placing of a flag in front of each ventilator and to accept its fluttering as an indication that all is well, as has been the custom in many schools, is to place reliance on a very poor index of efficiency. Moreover, all locker rooms or wardrobe spaces should be adequately ventilated. In this connection, it should be pointed out that the ordinary method of storing clothes is one which is not conducive to safety or good health, unless a proper amount of space exists between the clothing of each individual child, so that there may be no point of contact, and unless the space in which clothing is stored is well ventilated and well lighted. The sterilizing effect of sunlight not only upon the air of rooms which must be breathed by persons, but also upon the air of locker spaces must not be overlooked.

The air must not be discharged with velocity at some one point in a room to the inconvenience of some of its occupants but should be properly distributed throughout such room. Children who are seated near the windows in a room where natural ventilation is depended upon, should be guarded by a deflector—an inclined glass or wooden shield placed across the lower end of such windows, to deflect air currents entering such room upward so that they will not directly strike such children. In a similar fashion, children who are

seated near radiators or other heating devices may suffer from the effects of excessive heat. Such radiators should be properly insulated by non-conducting material (asbestos, etc.) and the heated air should be deflected upward, or better still, the radiators or heating units should be so distributed as to be at a distance from children's seats.

Absenteeism and Ventilation

In a study made by Dr. S. J. Baker, the director of the Bureau of Child Hygiene, it was shown that in the closed-window room which was ventilated mechanically and kept at a temperature of about 58 degrees F. the rate of absences as the result of respiratory disease was 32 per cent greater than in the open-window rooms which were naturally ventilated and kept at the same temperature. The best condition of health with respect to the prevalence of respiratory diseases is found to obtain in the open-window classes. At comparatively frequent intervals, as at the end of each period, all windows should be opened and ventilated, preferably while the children are for the time being out of the room, or, if they must be kept in the room, while the children are exercised. Frequent changes of air are not only conducive to better health and comfort but make for increased efficiency. Where mechanical methods of ventilation are depended upon, a "wet and dry bulb thermometer" should be supplied in each such room, and the teachers should be made familiar with the reading of such thermometers so that they may estimate the relative humidity which should be at least 20 per cent for any given temperature. A special chart or table is furnished with each such thermometer which enables the teacher after a very brief experience to make the necessary computation. For the average room, a temperature of 68 degrees F. is most desirable from the standpoint of health.

Lighting Features Important

While proper lighting has not the importance of ventilation in relation to health, it is nevertheless of considerable significance among pupils and teachers because it prevents eye strain. The latter condition may be responsible for serious suffering or discomfort which may be manifested by headache, irritability, lack of attention, fatigue, and be the cause of distant or so-called "reflex" disturbances which may be referred to the stomach or to other parts of the body.

Dr. Ralph E. Wager of the Department of Biology, Northern Illinois State Normal School, in his study of the health of teachers calls attention to the marked prevalence of defects of eyesight among them.

There can be little doubt that a defective system of lighting may not only react to make teachers and pupils irritable, restless, and fatigued, but that it may be responsible for the backwardness of many pupils. It is not sufficient to depend on visual tests to discover such defects of eyesight; it is infinitely better to correct improper lighting. Seating arrangements should be of such character that the light falls over the left shoulder, and the arrangements of seats as well as the location of blackboards should be ordered so that they may not be placed at an angle which interferes with vision and produces a glare. It can be stated definitely that where natural or artificial lighting is used, the writing surfaces, whether blackboards or desks, should be neither too brilliantly lighted so as to reflect glares, nor should there be marked shadows upon them. When artificial lights are employed, care must be taken that they should not flicker. Those who are in the habit of reading newspapers or books in the subways can testify to the blinding effects of flickering lights, recently so conspicuous, and they will readily understand how this condition may cause serious eye strain.

Engineering Requirements

In connection with adequate lighting, it is well to bear in mind the three requirements which are always insisted upon by leading engineers; namely, *sufficiency* and *continuity* of light, and *diffusion*. The sufficiency of light depends upon having an adequate window area. In order that there may be continuity, it is not only necessary to have a large enough window area for use on comparatively dark days, but there must be provided also one or two things—first, a way of reducing light when it is excessively bright, and second, a way of increasing or supplementing it when the days are dark as at the close of day in the winter season or on cloudy days. Lighting engineers emphasize the necessity of having rooms painted in light color, especially the ceilings and the upper portions of walls so that light will not be absorbed by dark surfaces, but be reflected and diffused throughout a room. The lower parts of walls should be painted dark to give relief to the eye. The diffusion of light

calls also for the proper placing or distribution of windows. If the requirements which were specified with reference to the area of window space per person under the head of ventilation are compiled with, the lighting requirements will at the same time be well met. Adequate natural lighting like natural ventilation, is the best. However, we must be careful to prevent the glare of sunshine. In such cases, window shades, especially those which can be raised from below upward, are essential. Windows that have a northern exposure are best for the purpose of lighting. Those that have a southern exposure permit an excessive amount of sunshine to enter during the middle of the day in particular, so that a heavy shade may have to be pulled down to cover the entire window area, thus necessitating the use of artificial lighting during the early part of the day. When sunlight enters through the upper part of the window, it may be modified and made agreeable by having translucent window glass put into the upper sash, or by using light, translucent shades. The light entering through the upper part of the window diffuses over the widest area in the room. For this reason it is desirable to have windows reach to as near the ceiling as possible. The opaque or dark window shade is undesirable. Windows must be kept clean or they will prevent the entrance of an adequate amount of light even though the total area of window space is sufficient.

If the windows look out upon a more or less confined space, and the light is intercepted or reduced by neighboring buildings much can be done to improve the lighting of such rooms by using what is known as prismatic glass. Prismatic glass is supplied in the form of corrugated glass or has little prism-like projections which catch the light from any patch of sky which such windows may face, and reflect or bend the light, and direct it into the room. While clean windows are always a most important essential for adequate lighting, they are of the greatest importance where prismatic or translucent glass is employed, because in these the light is already to a certain degree modified.

When artificial lights are employed, they must be properly distributed so as to give light to all parts of the room; they must be of adequate candle power, and the glare from such light which may fall upon polished desk-tops or other polished surfaces must be eliminated so far as possible

by the use of dull paints and by the proper shielding or shading of the light. The lamps that are supplied must be kept clean or a great deal of the lighting power is lost. The use for ground glass electric bulbs or of ground glass globes has found great favor and is very desirable because it prevents glare. Reflectors are extremely valuable in improving and distributing the light thrown by lamps but they are utterly useless if they are permitted to become unclean. It should also be remembered that a lamp which may give adequate candle power at the beginning becomes worn out with use, and the light therefore grows dimmer. If artificial light must be employed in a classroom, it is advisable not to depend on a single light or a cluster of lights placed in the center of the ceiling, but if possible such lights or clusters should be distributed about the walls or ceiling so as to light up equally well all parts of the room. Any system of artificial lighting which permits marked shadows to be thrown upon any part of the working space or particularly upon the desk, is objectionable and indicates that an improper system is employed. When artificial lighting is employed in classrooms, the optimum amount of light for ordinary use should be four foot candles. A foot candle is the common unit of illumination and is the amount of lighting effect produced upon an object by a standard candle held at a distance of one foot; roughly, one can estimate whether the four foot candles which ought ordinarily be supplied for office work have been furnished, by the following very simple mathematical test: The candle-power furnished by a lamp or cluster of lamps is made the numerator; the denominator is the square of the distance of such lamp or cluster of lamps, from the writing surface. For example, if a single lamp, or if a cluster of lamps in the center of the room, gives a light of 200 candle-power, then 200 is the numerator; if the distance from the writing surface of a pupils' desk to the source of light is ten feet then the square of the distance is one hundred feet and the denominator is therefore one hundred. We then have a lighting power of $200/100$ which equals two candle power; in other words, we have only half the optimum illumination. The minimum which should be allowed for close application is three foot candles; therefore, in the problem cited, the boy who sits ten feet from a two hundred foot candle light is receiving only one-half of the optimum, or two-

thirds of the minimum lighting required.

Drinking Fountains

All the standards that have been previously outlined have been in agreement with those which are laid down by authorities in the field of industrial hygiene for offices and similar work-places. Continuing to apply such standards, it ought to be emphasized that drinking water ought to be readily accessible on the various floors of school buildings, so that pupils and teachers may not have to lose time in going a considerable distance to slake their thirst. It is the general experience that where drinking water is not readily accessible, there is a tendency to repress the desire for water. The importance of drinking water in adequate amount from the health standpoint, as well as for the sake of comfort, need not be argued at this date. Nor need one dwell upon the dangers which lurk in the use of common drinking cups.

The placing of drinking fountains in sufficient number so as to be readily accessible, is the best means of eliminating the use of the common cup which is always present where the ordinary faucet is used to control the flow of water. The drinking fountain must, however, conform to a modern design or it may give a false sense of security with respect to the transmission of disease. Such fountain must deliver a column of water that rises to a height of several inches. It should be furnished with a metal ring which prevents any person from bringing the lips in close contact with the spout of the fountain. The column of water should not, however, be a vertical one, because it has been found by experience that disease germs which may be on the lips of a person who uses the fountain, may remain supported at the top of the column of water for a very considerable period of time without being discharged into the drain. For this reason, the only proper type of drinking fountain is one which delivers an inclined column of water rising to a height of several inches, the inclination being about 15 degrees, so that any germs which may be caught in such a column of water are not kept dancing at the top, as is the case with the vertical water spout, but fall over into the drain promptly.

Matters of Sanitation

Toilets should be readily accessible. A great deal of unnecessary loss of time results when toilets are housed in a single unit at a considerable dis-

tance from the classrooms or offices. Moreover, constipation which is of such frequent occurrence among all pupils, and among teachers whose life is a sedentary one, is encouraged when the toilets are at a considerable distance. This is the common experience with large groups of people in industry and undoubtedly applies to the school population.

It is needless to say that the sanitary standards in the construction and equipment of toilets should conform to those laid down for industry, that is, there should be a sufficient number of toilets for the school population; they should be so constructed that the ventilation, lighting, and heating conform to the standards already laid down; they should insure privacy, for it has generally been found that where there is no privacy, there is a tendency toward demoralization through the force of bad example and through the operation of perverted or "crowd" psychology. The material entering into the construction of the toilets should be impervious and non-corrosive, and the construction should allow for proper drainage so that there may be no stagnation or accumulation and exposure of excrement. The windows and doors of the toilets should be particularly shielded during the spring and summer time by the use of screens to prevent the entrance of flies.

It should be remembered that while one hundred eleven typhoid carriers are known in the city of New York, it has been estimated that from 3 to 5 per cent of those who have had typhoid fever remain typhoid carriers, discharging typhoid bacilli in their excrement for many years or for the rest of their lives. In the city of New York, we have had in the last ten years more than twenty-thousand recognized cases of typhoid fever which were reported to the Department of Health. It will be seen at a glance that there must be many more typhoid carriers, even if we limit ourselves to the cases which occurred in the last ten years, than are known to the Health Department. This may include many school teachers or pupils who recover or who may be healthy carriers. The entrance of flies which may have access to excrement that is not promptly and effectively washed away or drained, is therefore a possible source of danger. Therefore, the trough urinal or receptacle in toilets, or the so-called school sinks are a source of danger. Water-flushed and properly sewer-connected drainage is necessary. All

toilet fixtures, together with screens at windows and doors, are very essential to prevent the possible spread of typhoid fever, and of other intestinal diseases through the medium of flies.

Washing facilities in toilets should be adequate. Typhoid carriers are safe to others only to the degree in which they exercise care promptly and thoroughly to wash their hands. Therefore, washing facilities should be available in toilets or near toilets, and also in other parts of the building so as to be readily accessible. A variety of communicable diseases is no doubt transmitted as the result of infection of the hands through contact with the nose and mouth, as well as through possible soiling with human excrement. The supply of washing facilities, and the installation of hot water regulated so as to be of proper temperature, are extremely important from the standpoint of health to the individual pupil or teacher, and to those with whom they may come in contact. The supply of soap and towels in suitable quantity is also extremely important. Measures have been devised which permit one to provide these upon an economical and practical basis. Special paper towels, as well as properly secured cloth towels, are available on the market. It is more economical to prevent disease by supplying proper washing facilities as well as to inculcate proper personal habits in pupils, than to save money by omitting such facilities and fixtures.

General Cleanliness

Reference has already been made to the economy which results from keeping windows and lighting fixtures clean. The general cleanliness of floors and all furniture hardly needs to be alluded to in the light of modern knowledge. It is important that dry dusting and dry sweeping be eliminated from all schools, no matter at what hour performed, but especially before the opening of school or at any time during the school day. Dry dusting and sweeping tends only to scatter dust and is not effective for its collection and disposal. Mopping of the floors with oil-cloths or with damp cloths or so-called "set-tlers," like oil particles or wet sawdust, is essential and this should be done when the school has been completely emptied of pupils and teachers. In this connection, reference should be made to the chalk dust which is set free in class rooms or which results from the cleaning of erasers. This should be prevented so far as

possible by the use of moist cloths for erasing chalk marks. While this may involve loss of time, it is, however, profitable in the long run. Pupils should never be asked to clean blackboard erasers.

Rest and Lunch Rooms

In modern industry, it has been found not only desirable but necessary and economical to provide a lunch room where those who are unable for a variety of reasons to secure luncheon at their homes or in restaurants, may find suitable and sanitary quarters to be used as lunch rooms. While this is not important in the school as it is in certain branches of industry, nevertheless in the interest of good housekeeping and comfort, it is desirable so far as possible to have places which are available for use as lunch rooms for pupils and teachers. While a properly fitted up lunch room which has come to be recognized as an essential in the welfare work for those employed in industry, may be difficult to obtain in the schools, there can be no question whatever that a rest room suitably fitted up to permit pupils and teachers, who may be temporarily indisposed or ill, to rest, is necessary as well as desirable. Many absences which formerly occurred in industry because adequate facilities for rest or for emergency medical and nursing relief were lacking, have now been eliminated in industrial establishments which have regard for the health of employees. This has been done by the installation of rest rooms where nursing care or quiet can be obtained and where indispositions were promptly ministered to with the least degree of suffering to those who were so affected, and with the ultimate prevention of more serious developments. Rest rooms have been found to be a "paying proposition," to use the vernacular.

Unfortunately, it is not possible in the brief compass of an article of this character, to dwell upon the necessity for maintaining proper health in pupils and teachers by the observation of rules of personal hygiene which are extremely important, and which if violated will tend to weaken resistance or favor the development of disease. Much could be said about the value of an adequate and proper diet, faulty habits of eating, as well as the use and abuse of exercise, the need for rest periods, the value of adequate sleep, the avoidance of exposure to excessive heat and cold at various seasons of the year, and the relation of proper meth-

ods of dressing to such conditions. Attention to these details is required in the school, as well as outside of the school. The health aspects of recreation and many other topics which are directly related to personal health, might be profitably dwelt upon, but this address was not intended to emphasize these things.

By way of conclusion, it is desirable to refer again to the necessity for adequate medical supervision and study of teachers, with a view to ascertaining their physical condition and fitness at the time of their entrance into the profession, and of the casualties, and damages to health which may be recorded at various stages of their career in the profession, with a view to determining more accurately than has been done in the admittedly limited studies which have been made heretofore. There can be no doubt of the scientific value of studies which concern themselves not only with the results of medical examinations made at the time of entrance into the profession and repeated periodically thereafter, but of careful sickness reports, follow-up, and medical examinations to record the character, duration and the ultimate effects of all illnesses whether deemed trivial or important, conducted over a considerable period of time. In this way alone, will it be possible to obtain knowledge of scientific value and importance in safeguarding the health of teachers and protecting pupils from the physical and mental effects of sickness, to which their teachers may be subject.

Medicine Fails to Evaluate Physiotherapy

Research Has Come Out of the Chemical
Laboratory to the Great Out-of-Doors

BY FRANK B WYNN, M.D., INDIANAPOLIS, IND.

THE overweening influence of drug therapy for centuries past, perpetuated through both lay and professional prejudice, has militated against reforms and the introduction of other methods of treating disease. Dignified by age, endorsed by custom, and approved by the profession, medicinal therapy has frowned upon physical therapy as belonging to a lower class—suspected even of being non-professional. The physician who dared espouse these agencies with enthusiasm was at once suspected by the staid profession of having a mercenary ax to grind; if indeed he was not stigmatized as an out-and-out quack.

Use of Natural Forces

Under the term physiotherapy are comprehended those natural forces which, when properly applied, have to do with maintenance of health, comfort, and even life itself; or when misused or abused, are provocative of disease; and when carefully studied and skilfully applied become most valuable in a curative and preventive sense. Some of the more common of these are: Food and drink; air—cold or warm, stagnant or circulating, dry or moist; light, sunshine, darkness; water—by ingestion or hydrotherapy; heat or cold; exercise—graduated, active or passive; rest—mental or physical; isolation and seclusion; amusement and recreation; interest and occupation.

Have these things received the consideration at the hands of scientific medicine which their importance demands? Through all the tedious centuries of evolution in civilization, these things have, from necessity or choice, been employed, in disease, with real or supposed benefit to the patient. There is in all of us a deep ingrained faith in their efficacy. Whose memory does not hark back to the days of childhood, when a solicitous mother or the benevolent family doctor did not have recourse to them? Even now my senses are stirred by the memory of hot poultices—redolent with onions, mushy with bread and milk, or sticky with flax-seed; of tingling counterirritants and smelly fomentations; of dry heat and moist heat; of hot drinks and cold drinks; of gentle and affectionate hands stroking away pain or limbering up stiff joints; of cheering words and exhortation to patience, faith and grit to go through with a disagreeable job—all that complex which makes up the warp and woof of the childhood of ordinary folks.

Should the profession taboo these common domestic methods of treatment simply because they are universally employed? It were as wise to abandon the use of bread because almost universally eaten by the human race. Finer wisdom would be shown if we set about studying these common things scientifically and applying the knowledge in the conser-

vation of health and the cure of disease. Use them we all do, but how much systematic and thorough instruction concerning them did any student ever receive during his college course? Lengthy consideration and great emphasis were placed upon drug administration, surgical methods of relief, and recently vaccines and antitoxins, but as for physiotherapeutic measures—these are viewed as mere excusable fillings, designed to calm the mind of the patient, soften the tense anxiety of relatives, and make things easier for the medical attendant. These indisputable truths are strange commentaries on the defects of medical training. When we come honestly to weigh the truth, it is appalling the ignorance of the profession concerning these forces which we should utilize with the finest skill and the most acute intelligence.

As the Twig is Bent

A few common illustrations may be offered showing the usual bent of professional thought as to the relative value of pharmaceutical as against the physiotherapeutic methods.

A coated tongue, fetid breath, headache, and highly colored urine suggest toxemia, for which the vast majority of physicians will prescribe calomel followed by a saline—missing the larger factor in relief which would come from proper diet, free fluid ingestion, proctoclysis, and properly applied hydrotherapy.

A pale, wan child is secluded in a dark, stagnant room, given iron for its anemia, while its rebellious nature yearns for sunlight and the outdoors. It is taught to abhor circulating air, forgetful of the fact that this very movement of the air heightens its life and blood-making value, just as the ripples and cataracts purify water. It is fed upon broths, when nature craves the succulent, fresh vegetables and fruits—with their scouring, cleansing properties to the bowel, and their chlorophyll content, so potent in blood formation. This delicate child needs these natural blessings and it is one of the highest functions of the physician to know how to bring the little patient under their benign influence. In the early spring-time I plant indoors in boxes the tiny seed, which burst their protective coats, rupture the soil-crust, and thrust their white petals toward the light; actually leaning forward to receive the welcome sun rays; and finally exchanging their anemic palor for the sturdy, beautiful green of the growing plants. Is not this an eloquent sermon upon physiotherapy? Should we be less wise than the unthinking plants regarding the value of sunshine?

Think of the great army of American constipation! The vast majority of these innumerable hosts are women—devotees at the shrine of aloes and cascara. But do even these efficacious remedies work a cure? Let us rather say they establish a habit. If complete relief is to be enjoyed it must come chiefly through the proper application of physiotherapy—copious water ingestion, coarse, bulk-forming and succulent foods, which are both exercising and scouring to the intestines; and that form of bodily exercise which brings the abdominal muscles into frequent and prolonged activity. True, it is difficult to combat the social customs of modern times, the tendency of American women of the so-called upper classes to physical idleness and enervating pursuits. The easy and lucrative way for the profession is to fall in line with indolent habits, the pink teas, card clubs and whirl of social engagements with their irregular hours and excesses—and continue to prescribe laxatives as a routine.

A larger, more wholesome and more permanent service would be rendered the individual and the community by insistently inculcating the doctrine, and following it to execution, of more active participation in the physical labor of the household; of more frequent open-air recreations which de-

velop the muscular system, stimulate pride in physical accomplishments; or, better still, where possible, the cultivation of growing things—flowers, shrubs, fruits, vegetables, etc. More difficult, let us admit, is the execution of such a program than the writing of a prescription. The successful accomplishment of this task requires on the part of the physician, first, the art of persuasion; and secondly, a generalship which plans with far sight for the winning of the battle and brooks no deviation from the orders given. On the part of the patient there is demanded unwavering faith in the wisdom and sincerity of the medical commander and a firm determination to see the thing through to a successful finish. To break one of the habit of chronic constipation is a tedious and difficult task, and is worth a good price. If we would cure, rather than temporize with and cultivate it, we must proceed by the physiotherapeutic route.

Drugs or Self-Exertion?

Or the subject of consideration may be a successful man of affairs—desk-ridden; plethoric from overeating and underexercising; bowels rebellious under their load; liver enlarged, tender; the skin, icteric; throbbing heart, pounding headache, and high blood-pressure; a man keen, tense, ambitious for large results, and explosive under the nagging irritations of his great responsibilities—how is he to be treated? Shall we seek his relief by draining the gall bladder, chologogue purges, and hepatic stimulants? Should we reduce his blood-pressure by cardiac depressants, or remedies inducing vasomotor relaxation; relieve his headache by coal tar derivatives and quiet his nerves with bromids? One or the other of these things may be indicated. Or may we not with even greater wisdom map out for him an entirely new order of living—holding up perhaps for his temporary emulation the oriental philosophy of passivity rather than the restless, driving ambition of the occidental races; exhorting him to restful contemplation for the sake of his peace of mind; inviting him into the paths of tranquilizing Nature for his tired nerves; for the sweetening of his irritable disposition, suggest the fairyland of wonders and beauties found in the great outdoors.

Of all disease, what is comparable in vital interest, to both physician and layman, with pulmonary tuberculosis? So familiar is the world with its prevalence and ravages, that statistics need not be quoted. Only a few dec-

ades ago its hopeless gloom dampened the ardor of the physician and enshrouded the victim of this malady with despair. Quackery made easy prey of these pathetic sufferers, for in the current of despondency they grasped at straws. Under alluring promises they were persuaded to swallow benumbing narcotics, to induce rest, relieve cough or pain, and stimulants which aroused only artificial strength; finally sinking under the wave of mixed infection and toxemia.

Thanks to the discovery of its cause and a better understanding of its management, we now look upon pulmonary tuberculosis with hope, confident of its prevention, arrest or cure. What has wrought this marvelous improvement? Has it been through the legerdmain of a medicinal potion? Aside from the great value of opium in controlling cough, pain, and restlessness; the reactive tissue repair in some chronic conditions to iodine products, and the use of tonics, what claim can drug therapy make for the extraordinary advancement achieved in the management of pulmonary tuberculosis? Are we not bound to admit that the great blessings of progress in the treatment of this protean malady have come about almost entirely through physiotherapeutic factors; that is to say, in prevention and management we have come to a better understanding of the natural forces—air, sunlight, food, rest, exercise, recreation and occupation?

Methods Misapplied

Yet with these vast and convincing evidences of progress before the profession, can we truthfully claim that anything more than the most superficial study of these natural agencies has been made? It all seems so simple that we pass it over with trite instructions and immature thought as to details in working out the program. Thus, most unfortunately, the patient gets the impression that the whole scheme of procedure is so simple that the physician is not needed in carrying out the treatment. Taking things into his own hands, the layman fails properly to interpret symptoms and conditions; there is misapplication of physiotherapeutic procedure; and in the end disappointment and disaster result. To illustrate the point more fully:

At one juncture in the course of pulmonary tuberculosis, rest is imperative. Who should know this but the alert and trained physician? If progress towards cure is made, there must come an end even to rest in a

case. Again, who shall call the change to exercise but the experienced observer? Then arises the question of the kind of exercise; the frequency, amount, and the correct interpretation of the body reactions to varying grades of mental or physical activity. Thus it becomes evident that things apparently so simple call for the highest intelligence and judgment; the most painstaking and patient observation; and require most untiring and insistent direction. The successful management of a case of pulmonary tuberculosis, from its recognition, through the tedious years to its arrest or cure, constitutes one of the most difficult problems in medical practice. If gratifying results are attained, they are brought about not so much through drug administration as from the intelligent, patient and painstaking application of physiotherapeutic methods.

The failure of medical education adequately to instruct students upon these important phases of disease management necessarily places a handicap upon hospitals and training schools for nurses. Despite the enormous growth of hospitals in number and structural excellence, their improvement in artistic appearances, hotel conveniences, laboratory and surgical equipment, how many institutions have the physical equipment, for example, to make proper application of hydrotherapy? Must the public continue to depend upon Turkish-bath establishments for refreshing and health-giving hydrotherapy? Do not these latter constitute the physician's chief source of instruction upon this subject, rather than the medical schools or hospitals? How many trained or graduate nurses know anything about the therapeutic bath, other than for sanitary purposes; a cold sponge for hyperpyrexia; or a hot pack for grave toxic conditions? Let us not condemn nurses for these shortcomings, but rather confess our own lack of knowledge concerning the value and methods of hydrotherapy.

Exercise Works Wonders

Nearly akin to the foregoing are those physical manipulations comprehended under the term mechanotherapy. These include massage, Swedish movement; developing and upbuilding exercises, as in gymnasiums; correctional movements for orthopedic conditions; re-education exercises, as in the ataxia of *tabes dorsalis*. How many graduate nurses are capable of carrying out these technical procedures? That they do not understand

them is unfortunate; but how much greater the reflection on the medical schools and the profession!

Is it not to the discredit of medical colleges that most of our knowledge concerning these matters comes from the gymnasium and athletic field? Is there anyone of intelligence who has the temerity to claim such things have not extreme value? If such there were, has not the World War removed all question from the mind of the doubter? Who has not seen, by scores and by hundreds, lank, stoop-shouldered, anemic or sluggish youths march away to camp, from counters, shops, and desks, to return in a few months, erect, stalwart, manly looking fellows, with brawn in their muscles, courage written upon their faces, and hope gleaming from their eyes? What is the matter with medical education, if the physician is not able, day by day, to accomplish the same results, through somewhat similar agencies?

A Narrow View

In protest against the line of argument here offered, the voice of the average physician pleads as follows: "All that you say regarding the failure of medical schools to teach physiotherapeutics, and our ignorance upon these subjects, may be true; but have you paused to consider the monetary sacrifice to the physician which would arise from devoting large time to the carrying out of such measures? People are willing to pay for surgical attention, and for the routine care which involves the administration of medicinal remedies, but they have not been educated properly to evaluate these common natural forces in the management of disease. On our part it means tedious drudgery and poor pay in return."

Such is the prevailing obsession which has long controlled professional conduct. In answer to this line of argument let it be asked if the noted springs and health resorts where hydrotherapy has been emphasized have not yielded a substantial return? Some of these institutions have made commendable effort to set upon their methods the stamp of scientific and professional respectability. The majority, however, most strictly speaking, are only hotels and resting places. In some it is often saddening to find a good record dimmed by the grandiloquent claims of a mineral water. Even such institutions as the foregoing have scarcely kept pace with the public demand for accommodations. The foregoing commercial facts seem to be to controvert the professional fear that hydrotherapeutic methods will not pay.

On turning to manual therapy, as an avenue of lucrative return, is it not true that within the past ten years, quasi-professional men, chiefly of mediocre education, and the most brief and superficial training in the fundamental branches of science, have carried manual therapy to a point in public esteem where it receives credence and support from many intelligent laymen? There are five hundred chiropractors in Indiana alone, and two thousand students of chiropractic in an Iowa college. We cannot ridicule these sects out of existence. We may rail at their brazen pretense, declaim against their ignorance, and justly arraign their reckless action in treating serious cases which they know nothing about, but they go merrily on the highway to business success. Is the numerical growth and achievement of osteopathy and chiropractic merely the result of bold advertisement and humbug, or is there back of it all some germ of truth which we have overlooked or refused to see? If so limited a phase of physiotherapy can be made to pay financially by those poorly equipped, how much greater should be the monetary benefits which might be expected if well-trained physicians made scientific study and intelligent application of the broad problem of physiotherapy.

The Branch is Not Taught

The main purpose of this discussion is to show that the medical profession has failed to measure up to duty in the study and application of the common natural agencies, in relation to the cause and cure of disease. We have failed (1) because medical schools have not taught these things thoroughly or systematically; (2) because hospitals have not provided the facilities or a staff of instructors thoroughly competent to instruct; and (3) because nurses have not received efficient instruction in carrying out the methods. Foundations and endowments have been lavish in appropriations of money for the study of pathological and chemical problems relating to disease; but where have large sums been expended in the study of heat, cold, light, air, water, rest, exercise, manipulation, or vocation, in relation to disease? Our very neglect to give these subjects the attention they merit in therapy has been more responsible than aught else for the development of recent sects in medicine. If we would, therefore, prevent the tendency to erratic and sensational

offshoots from medicine, let us give no substantial excuse for their origin. Behold the rapidly increasing flood of irregular practitioners, most of them conscienceless pretenders or mercenary commercialists seeking shortcuts to the rights and privileges of med-

ical practice. Shall we allow them to possess the domains of legitimate medicine? However venal and commercial may be chiropractic and its kind, let not this fact prejudice us against the germ of truth they may contain. Our duty should be to gar-

ner the grain but cast out the chaff—educationally and professionally. Let the medical profession, aroused to full consciousness of duty, reclaim and cultivate with scientific and clinical thoroughness a neglected field—physiotherapy.

Organization for Public Health in Ohio

Efficient Organization Ultimately Means Less Sickness and Fewer Deaths Throughout the State

BY ROBERT G. PATERSON, PH.D., EXECUTIVE SECRETARY, OHIO PUBLIC HEALTH ASSOCIATION, COLUMBUS, O.

OHIO was one of the first states in this country to organize a voluntary association to combat tuberculosis. The Ohio Society for the Prevention of Tuberculosis was organized in 1902. Beginning with this date, the Society has been actively identified with every measure put forth to control tuberculosis in the state. As our experience and understanding of the problem grew, our interests widened, until at the present time the name of the Society has been changed to the Ohio Public Health Association to indicate publicly the new work which the Society desires to promote.

State Voluntary Organization

The Ohio Society for the Prevention of Tuberculosis was organized in the offices of the State Board of Health in 1902. Funds were raised through

membership dues. In addition to the educational work which was carried on, the Society initiated legislation which provided for a commission to study the feasibility of establishing a state sanatorium for tuberculosis; secured legislation for the establishment of the Ohio State Sanatorium; and was largely responsible for the passage of legislation for the establishment of county and later district tuberculosis hospitals. The period covered by this work was from 1902 to 1911 in which was laid the foundation for the future work of the Society.

In 1911 the Society began a new period in its life due to the advent of the Red Cross Christmas Seal as a means of raising funds for tuberculosis work. The Society was enabled to employ an executive secretary to devote his full time to the

work: a survey of the tuberculosis situation throughout the state was undertaken, a result of which led to the adoption of a program of work to be accomplished. Two items in that program to be noted at this time were the inclusion of tuberculosis as a notifiable disease by the State Board of Health in 1912 and the appropriation of twenty thousand dollars a year for the establishment of a bureau of tuberculosis in the State Board of Health organization in 1913.

This Bureau was the first of its kind in the United States and its establishment at the time led to many misgivings on the part of tuberculosis workers that politics would play an important rôle in determining the future tuberculosis work in Ohio. These misgivings have proved to be unfounded. The greater gains to the tuberculosis campaign by having funds provided out of taxation for carrying on the various forms of work which have been tested and proven successful is generally accepted today.

At the present time the program of the Ohio Public Health Association includes plans to:

- (1) Supplement and assist the State Department of Health.
- (2) Establish local public health leagues paralleling the local official health organization to accomplish locally the same results which the State Association strives to obtain on a state-wide basis.
- (3) Develop a state system of public health nursing.
- (4) Assist the Ohio State University in the establishment and conduct of courses for the training of health officers and public health nurses.
- (5) Coordinate a program of public health legislation.
- (6) Carry on a continuous campaign for the prevention of tuberculosis and conduct educational propaganda on public health matters.

An important step in advance in health work in Ohio took place when the Wright Bill to reorganize our

Typical cottage at the Ohio State Sanatorium, Mount Vernon, O.

State health administration became a law in 1917. This law abolished the State Board of Health consisting of seven members appointed by the Governor. Each member was appointed for a term of seven years, one appointment being made each year. The Board appointed the secretary annually and he served as the state health officer. The laws of Ohio placed practically all of the executive power in the Board, which made it necessary to await the convening of the Board in regular or special session before matters could be decided. The law of 1917 created a State Department of Health consisting of a public health council of four members and the State Commissioner of Health. Council members were appointed by the Governor for a term of four years, one appointment being made each year. The Council elected the State Health Commissioner for a term of five years and the Governor approved his election. The executive and administrative functions of the State Department of Health were lodged with the State Commissioner of Health. The legislative and judicial functions were placed with the Public Health Council. This change has made it possible to accelerate the administrative health work of the state to a degree impossible under the former plan of organization. Under a general reorganization of state departments authorized by the Legislature, effective July 1, 1921, the method of appointment of the State Health Commissioner was changed. The reorganization bill provides for appointment of a State Director of Health by the governor for a term co-extensive with that of the governor, retaining the public health council with legislative and judicial powers only. This change was opposed by the public health organizations of the state. The term of the governor is limited to two years under the constitution, which means that there will likely be a change in the office of director of health with each change of administration. There is strong sentiment in the state for a change in this law which will insure a longer tenure of office for the head of the state Health Department and keep the health machinery of the state free from partisan politics.

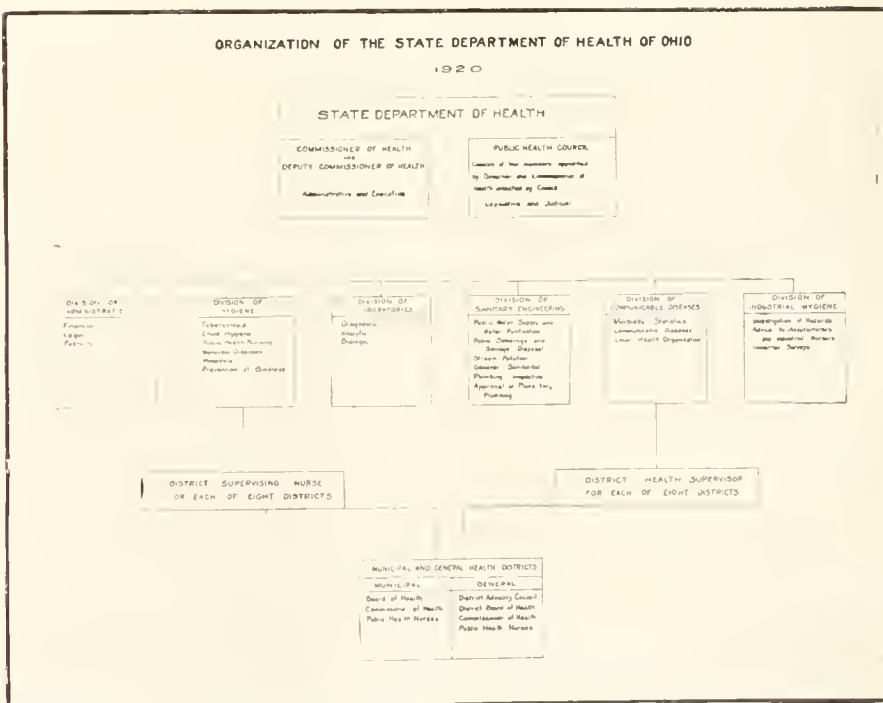

The next item in the program embraced an entire reorganization of the local health administration under the Hughes-Griswold Law of 1919. There were 2,150 health districts in Ohio under the old law. Every township board of trustees constituted a board of health. Every incorporated

municipality had a board of health. The actual results of this system were five full time health officers and the remaining 2,145 health districts in the hands of part time men who had no previous qualifications other than that they happened to be clerks of the board of township trustees or practising physicians willing to assume the responsibilities in the municipalities for little or no compensation. Under this system, while the legal responsibilities for providing health protection were lodged with local authorities, the actual burden was placed with the state authorities because of the absolute inability of the local boards of health and their health officers to meet the situations which confronted them. The Hughes-Griswold Law provides for a general health district in each county in the state embracing all the territory in the county outside of municipalities. Each city of five thousand or more population is created a municipal health district. Each general health district has a board of health of five members which appoints the health commissioner. There are eighty-eight general health districts as provided by the law. Two districts have no health commissioner. Eighty-six have health commissioners. Seven general health districts have combined with municipal health districts and jointly employ their health commissioner. Of the remaining seventy-nine general health districts,

forty-two have full time and thirty-seven part time health commissioners. All of these commissioners are physicians, as required by law. There are eighty-one municipal health districts. Seven have joint commissioners with the general health district, sixteen are full time and fifty-eight are part time commissioners. While a majority of the commissioners are physicians, the law does not require that they shall be.

The ultimate effect of this reorganization in reducing the mere number of local health authorities from 2,150 to 169—eighty-eight general health districts and eighty-one municipal health districts—with the increase in efficiency of the local authorities in dealing with local health problems, can lead in due time to but one thing; less sickness and fewer deaths throughout the state.

One of the most important items in the program of the Ohio Society for the Prevention of Tuberculosis adopted in 1911 was the belief in the public health nurse as a vastly superior agent in the prevention of disease over the prevailing type of sanitary officer. In the year 1911 there were twenty-five public health nurses employed in nine cities in the state. The Ohio Society began the development of a state system of public health nursing by advocating the employment of public health nurses by the local anti-tuberculosis societies. Legislation was secured to make it pos-

Reorganization of the public health work of Ohio as effected under the Wright Bill of 1917. Members of the Council are appointed by the governor, one each year, serving for a term of four years.

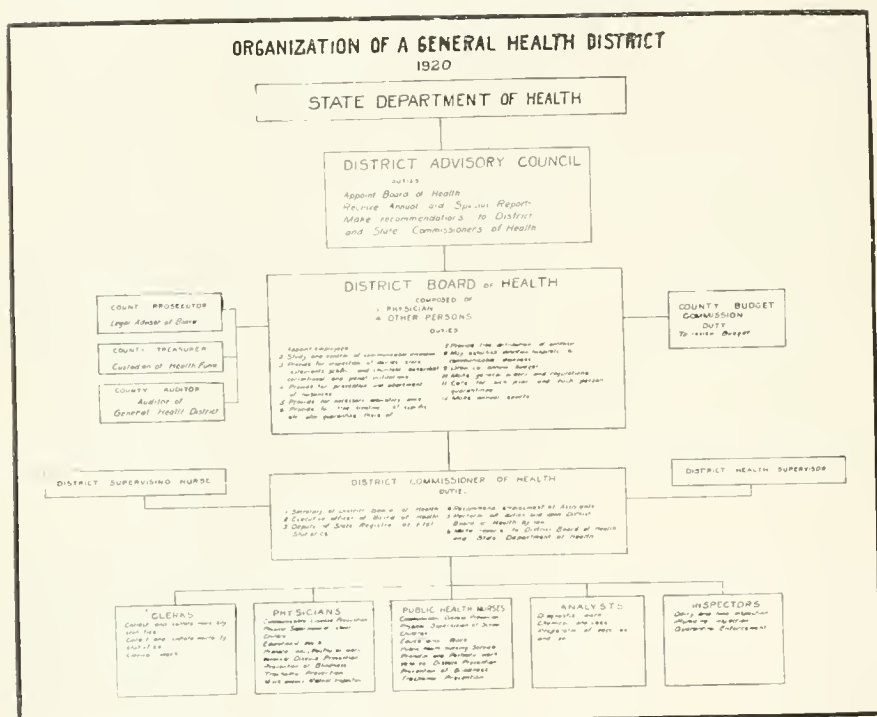

sible to employ public health nurses by county and district tuberculosis hospitals; municipal boards of health; and by local boards of education. In the establishment of the bureau of tuberculosis in the State Board of Health in 1913 provision was made for the employment of one nurse as state supervising nurse. Finally, in the Hughes-Griswold Health Law, three employees are mandatory, a health commissioner, a clerk, and a public health nurse.

From the standpoint of the prevention of disease and the protection of the public health, the writing into the law of the public health nurse as an essential employee of the local health organization gives promise as one of the most important steps yet taken in Ohio to reach promptly and

in that administration, forces the problem of personnel forward as the most important factor in the success of the system in Ohio. Steps to meet the problem were taken in 1915 when the Department of Public Health and Sanitation was created in the College of Medicine by the Board of Trustees of the Ohio State University. A course was established for health administrators and a course for public health nurses. In 1916 a combined course in science nursing covering five years was established. This course leads to a bachelor of science degree and a nursing diploma. The teaching staff now includes three public health men and two public health nurses. One great obstacle in the rapid development of these courses has been the lack of hospital

The legislature of Ohio meets every two years. At every session of the legislature constructive and destructive proposals are embodied in bills seeking to alter existing methods of dealing with public health matters. In addition, the physicians, dentists, druggists, and nurses are constantly on the defensive to prevent the breaking down of existing professional standards and on the offensive to endeavor to raise the requirements for admission to their ranks. Working separately through their state associations, each register gains and loses every legislative year. The clash of these interests before legislative committees has created confusion in the minds of the average legislator, to the detriment of all public health legislation. A distinct step in Ohio was achieved in 1914 when the various professional groups were united in the Ohio Public Health Federation. The common meeting ground for them all has been on the public health aspects of their legislative programs. There are twelve state organizations represented in the Federation—the State Federation of Women's Clubs, State Nurses' Association, State Medical Association—regular, homeopathic, eclectic, osteopathic, and veterinary—State Dental Society, Funeral Directors, Hospital Association and the Ohio Public Health Association. The Federation is financed through a per capita assessment upon the paid membership in each state association. All legislative proposals are considered by a central council consisting of one representative from each of the constituent associations. Unanimous action by the council is required to secure the full support of the Federation upon each proposal. In the event unanimous action is not possible, the state associations are left free to pursue such course as their interests seem to dictate. The result has been that many proposals have received the unanimous and intelligent support of all these state organizations—a condition which was practically impossible in former years. Furthermore, the Federation has succeeded in securing the passage of most of our constructive public health legislation.

In the campaign for the prevention of tuberculosis, provision has been made by law in Ohio for the establishment of a bureau of tuberculosis in the State Department of Health; the Ohio State Sanatorium; district and county tuberculosis hospitals; dispensaries; and public health nurses. The Ohio Public Health Association

Reorganization of local agencies effected under the Hughes-Griswold Law of 1919, under which redistricting covered the whole field and simplified administration under joint health commissioners.

intelligently the foci of disease infection throughout the state. At the present writing there are eight nurses in the bureau of public health nursing of the State Department of Health and 654 nurses employed by local health organizations. Demands for additional nurses are increasing apace in every section of Ohio, so that our hope that every home in the state shall have available the services of a public health nurse appears quite possible of realization within the next decade.

The reorganization of state and local health administration and the basic use of the public health nurse

facilities under the entire control of the University. However, this obstacle is to disappear within the next two years, since the legislature has provided funds to begin the development of a modern college of medicine on the University campus. The Ohio Public Health Association has taken an active part in various ways in making possible the growth of these courses. It is our belief that ultimately the State University in co-operation with the State Department of Health will be able to provide well trained men and women to fill the positions in the state and local health departments.

The Tuberculosis Sanatorium at Warrenville, O., serving Cleveland and Cuyahoga Counties, is an outstanding demonstration of right method.

is engaged in the task of securing local support for the appropriation of money raised by taxation for all of the foregoing purposes. In addition, the Association is carrying on a program of health education in the schools of the state through the Modern Health Crusade sponsored by the National Tuberculosis Association. The end in view is the adoption of a health curriculum as a part of the state system of education under the supervision of the State Superintendent of Education. One method adopted to secure this result is through the pageant, "Health Wins!" which has been specially prepared and produced for the Association. The pageant is given in local communities throughout Ohio and is dependent for its success upon the cooperation of

the school authorities, and the school children. It is expected that sufficient support will be developed at the next session of the legislature to secure the adoption of the health curriculum and sufficient appropriations for its supervision by the State Superintendent of Education.

The guiding principle adopted by the Ohio Public Health Association ten years ago has been that public health work, to be successful on a large scale, must be financed out of public taxation. The function of the voluntary health organization is to initiate and demonstrate methods and then to secure their adoption by the state through legislation and taxation. The state voluntary associations as well as local voluntary leagues must keep their organizations

free from official control. Their primary purpose is to aid the state and local health officials in building up their organizations and then in maintaining them.

Infantile Paralysis—A Message to Parents

The Visiting Nurse Association of Chicago has issued a booklet which summarizes authoritatively the nature, symptoms, and ravages of epidemic poliomyelitis as a word of warning and of helpful guidance to parents who are thereby enabled to recognize early signs of the disorder. Methods of treatment are described and muscle training advocated.

American Institute of Baking Properly Housed

THE American Institute of Baking, organized in 1919 for the purpose of placing the baking industry on a scientific basis, made a report of achievement at the Twenty-fourth Annual Convention of the Baking Industries held in Chicago September 20-22, 1921, which shows the immediate advantage both to the trade and to the public served in this provision of technical facilities for research. To the work of investigating the "chemical, physical, and biological problems which underlie the art and science of bread making" a service is being built up for consultation, advice, and critical examination on chemical, technical, and engineering subjects. On the nutritional side the study involves the precise analysis of physiochemical properties of flours and their baking qualities; examination of all shortening materials, of yeast food, and of milk products. The purely chemical work is supplemented on the bakers' side by the problems of engineering, building construction, power, heating, ventilation, wrapping, etc.

It is expected that the work of the Institute will be greatly facilitated by being housed in its permanent and adequately equipped laboratory home in Chicago. The property acquired consists of a three-story and basement building with ample room for expansion to meet the needs of the Institute for many years to come.

The Board of Governors has as its chairman, George S. Ward, of New York. Dr. H. E. Barnard is resident director of the Institute. The Institute will move from Minneapolis to its new home on or before January 1, 1922.

These tuberculous children are being treated by heliotherapy at the Franklin County Tuberculosis Sanatorium

Health and the League of Nations

By C.-E. A. WINSLOW, DR. P.H., PROFESSOR OF PUBLIC HEALTH, YALE SCHOOL OF MEDICINE, LATE DIRECTOR OF THE DEPARTMENT OF HEALTH, LEAGUE OF RED CROSS SOCIETIES, GENEVA, SWITZERLAND

WHEN the Covenant of the League of Nations was first drafted it was realized that one of the many important tasks of the new machinery of international cooperation to be created was the promotion of the cause of public health. The need for an effective agency in this field to assist in the standardization of vital statistics, in the collection and dissemination of information in regard to the prevalence of epidemic disease, in the development of port sanitation, in the negotiation of international sanitary agreements and in dealing with public health emergencies of international importance was obviously an urgent one. The *Office International d'Hygiène Publique* in Paris, operating under the Convention of Rome drawn up in 1907, was well equipped, from a statutory standpoint, to fulfill many of these functions, but certain important nations are not members of the *Office* and the financial resources of the organization are wholly inadequate for the effective exercise of any of them. The Covenant therefore constructed its new international health organization upon the foundation of the existing *Office*, which was to serve as the General Committee of the new organization and to appoint six of the thirteen members of the standing Health Committee of the League. The advantages of the plan proposed were so obvious that it was approved by all public health workers without reserve and was to have been put into execution last June.

The plan for formal cooperation proposed in the Covenant required certain minor modifications in the Convention of Rome; and the United States, in pursuance of the unfortunate policy of blocking the work of the League of Nations in force at that time, refused (as one of the signatories of the Convention of Rome) to permit these modifications to be made. For a time it seemed as if the whole ideal of an effective, international health organization must be abandoned. Technicalities have, however, happily proved powerless to prevent an understanding, demanded by the common sense and mutual good feeling of all the forces vitally concerned. On the initiative of a preliminary conference of certain members of the proposed new Health Com-

The matters which have commanded the attention of the health agencies of the League of Nations are proof positive of the necessity for international health organization. The concrete results of their deliberation are the earnest of the permanent value of the service.

Only when the scientific attitude is universally assumed will our neighbors cease to be a health menace. Only when all facts are in will disease control become feasible. An international clearing house of health knowledge would make effectual the emergent health functions of international health machinery and develop and standardize public health information.

mittee of the League, held in Paris on May 5th, the Council of the League appointed as permanent health secretary, Dr. Rajchman, the brilliant chief of the Polish Health Services, and named a Provisional Health Committee, of members who were to serve in their individual professional capacity, but who were at the same time so selected as to include all the factors to have been represented on the Committee projected in the Covenant.

Provisional Health Committee

The actual membership was as follows:

Prof. Leon Bernard, Professor of Hygiene, University of Paris.

Dr. G. S. Buchanan, Senior Medical Officer, British Ministry of Health, London.

Prof. Albert Calmette, Institut Pasteur, Paris.

Dr. Carozzi, Medical Director, International Labor Bureau.

Dr. Carriere, Director General, Swiss Public Health Service.

Sir H. Charles, President of the Medical Board for India.

Dr. Chodzko, Minister of Health, Poland.

Dr. Lutrario, Director General, Italian Public Health Service.

Dr. T. H. Madsen, Director of the State Institute of Serotherapy, Copenhagen.

Dr. Miyajama, Mitasato Institute for Infectious Diseases, Tokio.

Dr. Pulido, President of the Royal Council of Public Health, Spain.

Monsieur O. Velghe, Director General of the Belgian Public Health Service.

Prof. C.-E. A. Winslow, Medical Director, League of Red Cross Societies.

At its first meeting in Geneva, August 25-29, Dr. Madsen was chosen chairman of the Committee and Dr. Buchanan, vice-chairman.

The first question to be decided by the Committee was of course its relation to the *Office International* at Paris. It was clear, on the one hand, that the League of Nations must have its own health organization to advise in regard to the numerous health problems which come before it and that this organization, with modest but adequate funds and machinery for rapid action, would fill a pressing need for international service. On the other hand, it was essential to avoid conflict or duplication and to obtain the invaluable counsel of the large and democratically representative group of health administrators which constitutes the *Office*. Nine of the thirteen members of the new Health Committee of the League were also members (and among the most influential members) of the Committee of the *Office* and the spirit of mutual good will manifested by the representatives of ten nations gathered about the green table in the Palais des Nations at Geneva was nothing less than inspiring. Without a single echo of selfish interest it was agreed that cooperation must be brought about and effective methods devised for a relation between the *Office* and the League along the general lines laid down in the Covenant, but to be effected by voluntary agreement without the formal statutory changes which the attitude of Washington had made impossible.

The New Organization

In the words of the resolutions finally adopted at Geneva:

According to the Resolution of December 10, 1920, the Permanent Committee of the *Office International d'Hygiène Publique* at Paris, which includes the representatives of some thirty-nine countries—in most instances important administrative officers in the Health Departments of these countries—would, with certain additions, have become the General Committee of the Health Organization of the League. We consider that no health organization for public health purposes can be satisfactory to the League, which is not based on consultation with such a body as this. International measures for the

amelioration of the public health require both the collective deliberation of the responsible public health experts in the different countries concerned, and the direct participation of such experts, to the greatest possible extent, in any international work which affects the administration of public health in their respective countries.

Accordingly, the Committee has considered whether it is possible, without placing the *Office International d'Hygiene Publique* under the direction of the League, for the League to avail itself of the services of that office under its present constitution as a consultative body essential to the work which the Health Committee has in view and to the health duties of the League under the Covenant. They are happy to find that no obstacles exist. The Committee of the *Office International d'Hygiene Publique* is authorized, under the Convention of Rome, 1907, to undertake the consideration of any questions of health of international importance, and has already on several occasions stated its willingness to lend its assistance to the League of Nations and to cooperate in the consideration of any health questions which the League may care to submit. This declaration was last formally made by the President of the Committee of the *Office International* to the Secretary General of the League of Nations in a letter dated April 27th, 1921.

The new organization therefore includes (1) A health Secretariat within the League of Nations (including Dr. Rajchman and his staff). (2) The Health Committee of the League which will serve as an executive body and will be qualified to deal with all matters requiring quick solution. (3) The permanent Committee of the *Office International d'Hygiene Publique*, outside the League, but serving by mutual consent as the deliberative body to which important questions may be referred for advice and counsel.

In regard to the constitution of the Secretariat it was decided at Geneva that the first step to be taken was the development of machinery for the prompt collection and dissemination of intelligence in regard to the prevalence of epidemic diseases of international importance and that the establishment in the Secretariat of a Service of Epidemic Intelligence and Sanitary Statistics should be undertaken at once. The division of Vital Statistics of the League of Red Cross Societies, under the direction of Mr. Knud Stouman, has been for two years working along somewhat these lines but it has been long felt that the League of Nations rather than the League of Red Cross Societies was the proper body to undertake work of this kind. Mr. Stouman and his staff have therefore been transferred

to the League of Nations and attached to Dr. Rajchman's secretariat to perform the service indicated above.

A second urgent matter which came before the Committee was the problem of epidemic disease in Eastern Europe. For nearly a year the League of Nations has had a special Epidemic Commission—under the direction of Dr. Norman White—carrying on a most important work in the control of typhus in Poland and now that the Health Committee of the League has been organized the Typhus Commission is to be officially connected with it. The need for famine relief in Russia has at last opened that country to missions from Western Europe but nothing definite is as yet known in regard to the actual prevalence of plague and cholera in that unhappy country. It was therefore decided to send a medical mission to obtain first hand information; and Dr. White and Dr. Rajchman left for Moscow shortly after the August meeting.

Problems Are Diverse

Finally, to illustrate the diversity of the problems which the Health Committee must meet, mention should be made of a request from the Advisory Committee of the League on Traffic in Opium for an estimate of the average requirement of opium and related drugs for medicinal and other legitimate purposes as a basis for its work on the restriction of the production and interchange of such drugs. While recognizing the great difficulties involved in the task, the

Health Committee undertook a preliminary study in certain selected countries through a special subcommittee appointed for the purpose.

The potential importance of the new international health machinery created at Geneva can scarcely be exaggerated and the good wishes of all American public health experts will be with Dr. Rajchman in his difficult task. He assumes office on November first, the work remaining meanwhile in the hands of Dr. Steegeman of the British Ministry of Health who has for eight months been at the *Palais des Nations* as provisional Health Secretary pending the permanent organization now at last completed. To Dr. Steegeman and Dr. Buchanan, to Prof. Bernard, Dr. Madsen, Dr. Lutrario and M. Velghe and, above all, to Dame Rachel Crowley, with whose secretariat the temporary health work has heretofore been affiliated, belongs the lion's share of the credit for the happy consummation at last attained.

Red Cross in Porto Rico

The Porto Rico Chapter of the Junior Red Cross has established the first fresh air camp on the island. A recent fire in the city of San Juan made many of the families homeless. The Welfare Bureau of the American Red Cross found that large numbers of children among these families were in need of fresh air. This was brought to the attention of the Juniors who voted to send the children to the mountains. One hundred children will be cared for by three teachers during their vacation.

Campaign for Cancer Control

WHATEVER the message, whether scientific or secular, whether vital or of indifferent value, it takes hold largely in the degree that its publicity is well planned. It is chiefly on this account that the efforts of the American Society for the Control of Cancer is of such importance as a preventive medicine campaign.

The important laboratory studies of cancer in recent years have developed a mass of facts, and better records and general surveys have brought together an immense amount of valuable data that are at last being organized and properly presented to the public. During the intensive campaign conducted all over the United States and Canada from October 30 to November 5, valuable help was extended to lo-

cal organizations by means of literature, programs planned, and authoritative speakers furnished by the Society. Impetus was given to the whole subject of cancer control, especially through the cooperation consequent to the enlightened public interest growing out of their broadened information. It is significant, states the Society, that the death rate from cancer has been arrested. Since 1916 it has remained practically stationary, with only minor fluctuations. This is the most encouraging thing which has happened since the Society was organized in 1913, and leads them to believe that united effort by all cooperating agencies will not only prevent a further increase in this rate, but will effect a continuous decrease.

Drug Addiction as an International Problem

By JACOB A. GOLDBERG, A.M., PH.D., DIRECTOR, JEWISH BUREAU FOR HEALTH INFORMATION AND SERVICE, NEW YORK CITY

A FEW months ago there appeared in the pages of one of the literary journals an article from the pen of a physician of high standing in his particular branch of the medical profession. This article, entitled "The Drug Habit in the United States," took occasion to criticize what was believed to be the exaggerated statements regarding the extent of drug addiction in this country.

The author of the article in question stated that at the draft boards, the total number of addicts discovered was 1,000, while 2,120 were found by neuropsychiatric officers at the camps and recruit depots—3,120 in all, out of approximately 3,500,000 men examined. Furthermore, assuming that ten million men would have been examined, other things being equal, there would have been about 9,360 male drug addicts, which would have represented more than the bulk of the male drug addicts in the country. It is the opinion of a number of authorities that the number of women addicts in the country is in all probability far below that of the number of men.

It is in order to question the above figures that the following facts are presented. Under the Tennessee Anti-Narcotic Law in 1913, Lucius P. Brown, then State Food and Drug Commissioner, found that within a year there were registered under the provisions of the Act 2,370 persons. The state of Tennessee contains slightly more than 2 per cent of the total population of the United States, and on the supposition that the same ratio of addicts held good throughout the country there would have been a total of more than 118,000 drug habitués in that year. Let us consider more recent figures of another kind. The *Monthly Summary of Foreign Commerce* of the United States, December, 1920, states that in the year 1920 there were 1,462 importers, manufacturers, and compounders of narcotics; 4,679 wholesale dealers; 57,793 retail dealers; and 235,330 practitioners licensed to dispense opium, morphin, cocain, etc. Furthermore, under the provisions of the Harrison Law there were issued during that year no less than 2,163,200 opium order blanks; also, during the same year there were no less than 3,477 convictions for violations of the

Preliminary study now under way in certain selected countries is being directed by sub-committees of the Advisory Committee of the League of Nations on Traffic in Opium with the object of arriving at a satisfactory estimate of what may reasonably be regarded as the average requirement of opium and related drugs for medicinal and other legitimate purposes. Only in this way can be effected the equitable restriction of the production and interchange of such drugs. The question of drug addiction is a social medical problem, national in scope and international in its ultimate bearings.

Harrison Law, for other than delinquent payments of the special tax and presumably for the illicit sale and distribution of narcotics.

Several years ago a committee of the American Pharmaceutical Association estimated that there were approximately two hundred thousand drug addicts in the country, these figures being based upon a consideration of the amount of narcotics definitely known to have been consumed. This Committee further estimated that the amount of narcotics actually needed for legitimate medicinal purposes in any given year did not exceed sixty thousand ounces.

In the year 1909 the amount of crude opium legally imported into the United States was 465,776 pounds. In 1919 the amount was 730,272 pounds, whereas in 1920, for some reason, the importations fell to 211,277 pounds. Since one pound of crude opium yields an ounce or more of the refined product, morphin, it is apparent that the amount of morphin consumed is far beyond the necessary and legitimate needs of the country. The figures presented consider only opium and its derivatives; cocain and its derivatives contribute approximately a sixth of the number of doses as does opium and its derivatives.

It has been found that the average consumption per day of morphin addicts is about 8.5 grains, or approximately six and a half ounces per

year. Assuming that the great bulk of the ten thousand drug addicts mentioned in the article criticised were morphin addicts, they would consume about 65,000 ounces of morphin a year. In view of this figure, what happened to 675,000 ounces of morphin in 1919 and to approximately 150,000 ounces in 1920? By adding to this the large amount of cocain and its derivatives definitely known to be consumed by addicts, the total is even more impressive. A recent Federal report stated that the amount of narcotics annually smuggled into the country was at least equivalent to the amount legally declared. Granted that this estimate is excessive, there is an additional large quantity of narcotics still unaccounted for.

In view of all the facts presented above, there can be but one of two explanations. The figures arrived at in the article alluded to must be very far from the actual number of addicts in the country, or the amount of narcotics consumed through the agency of patent medicines is very large. In either case, the result is the same. The author of this paper cannot help but believe that, after due allowance has been made for the amount that enters into patent medicines, and the quantity legitimately used, there is still a very large quantity which is put to but one use, and that is, consumption by so-called drug addicts.

A correct understanding and knowledge of the extent of narcotic drug addiction in the United States at the present time is of much importance. Under the organization of the League of Nations there is an Advisory Commission on Opium Traffic. Sooner or later the United States will enter the League. If the facts as presented by the article in question are correct, then there is no real problem of drug addiction in this country, and future action regarding this social ill in the United States requires no official action other than that already taken. However, by accepting the other group of figures, we are led to a realization of a definite social problem that requires active American representation on a new international commission, just as we were represented in the Shanghai and Hague meetings in former years.

National Red Cross Convention

BY FRANCIS J. CARMODY, AMERICAN RED CROSS, WASHINGTON, D. C.

HOW the efficiency of the American Red Cross in its various fields of service may be increased and its scope enlarged was the general theme of discussion at the National Red Cross Convention in Columbus, O., just concluded. The Convention, bringing together representatives from the National Headquarters in Washington and Red Cross Chapters from Maine to California as well as lay speakers of national and international prominence, offered unusual opportunity for an interchange of views and experiences in the practical application of the manifold phases of Red Cross service in peace time.

While it is yet early to state definitely what will be the practical results of this first National Convention, it can be said with definiteness that it has served, as no other Red Cross gathering in the past has served, to bring with a new and greater emphasis a strengthening of the spirit of service that is the very fabric of the Red Cross.

A Statement of Purpose

Dr. Livingston Farrand, retiring Chairman of the Central Committee of the Red Cross, who has accepted the presidency of Cornell University, voiced the purpose of the Convention in his address on the opening night, Tuesday, October 4, when he said:

The purpose of the Red Cross, the purpose of this new Red Cross, is to seize that spirit of service which was brought out in such untold measure during the war—is to seize that and preserve it for the welfare of our American democracy to whatever extent possible. That is precisely the reason for this convention, for this gathering of delegates from every part of the United States, actuated, we believe, by the soundest of motives, simply by the desire to give service, to perpetuate something of that spirit of idealism that came out through the war, and to prevent the reaction that followed the war from swamping our American people.

The Convention was divided into two sections, mass meetings given over to the discussion of the broad general policies of the American Red Cross by nationally prominent speakers, and sectional conferences in which the Chapter delegates were gathered for a discussion of the technical phases of the individual services of the Red Cross.

Of the mass meetings in the Coliseum, there were five, including the

John Barton Payne, the newly appointed chairman of the central committee of the American Red Cross, has a long and honorable record in public service, and brings to his new office well proved ability as an executive and broad experience in welfare and recreational work.

opening session. The meeting devoted to a discussion of the Junior Red Cross, on Wednesday afternoon, presented to the delegates such notable educators as Henry Noble McCracken, president of Vassar College; Miss Charl Williams, president of the National Education Association; Dr. John H. Finley, and others.

"Veterans' Night," Wednesday, given the most prominent place on the program, attracted the most enthusiastic gathering of the week. That Red Cross service for the disabled man must be continued with ever increasing effectiveness and that its efforts in this field were greatly helpful and gratefully received by the Government and veterans alike was brought out by speakers representing the War and Navy Departments and Marine Corps, American Legion, and Veterans of Foreign Wars.

Ten minute speeches on "America's Obligation to Her Service Men and Women," at this session were delivered by Maj. Gen. John A. Lejuene, Commandant, U. S. M. C.; Dr. Thomas E. Green, American Red Cross; Capt. Robert G. Woodside, Commander-in-Chief of the Veterans of Foreign Wars; Rev. Francis P. Duffy, chaplain of the 165th Regiment; Rear Admiral Robert E. Coontz, United States Navy; W. Frank Persons, vice-chairman, American Red Cross; John G. Emery, National Commander of the American Legion; and J. Mayhew Wainwright, Assistant Secretary of War. A letter was read from General John J. Pershing, who had intended to address the meeting but who was unable to do so by reason of his trip to Europe, in which he extolled the work of the Red Cross in behalf of the service man, was read.

Central view of the exhibit hall at the National Convention of the American Red Cross, Columbus, O., October 4-8, 1921

Dr. William A. Evans, of Chicago, former president of the American Public Health Association, was a speaker at the Thursday morning mass meeting, which was given over to a general discussion of Red Cross services. Miss Annie W. Goodrich, assistant professor, Department of Nursing and Health, Teachers College, New York, and Miss Lillian D. Wald, president of the Henry Street Settlement, New York, were other speakers on the Thursday morning program who discussed the nursing and health features of the Red Cross.

"The Red Cross is peculiarly well circumstanced to assist in increasing human efficiency by promoting safety first and other accident prevention work," said Dr. Evans. "In the education of the people and by securing public interest which results in changing habits and customs, it has great possibilities. It can do much to aid in the fight against organic cardiac and arterial disease, organic renal disease and in the promotion of human efficiency."

Public Health Nursing

Discussing the public health nursing activities of the Red Cross, Miss Wald pointed out that "this great new field of constructive service sustained from day to day, month to month, and year to year, calls for conviction and for principles of service, rather than for an emotional reaction sure to be ephemeral in its character when not rationalized into a conception of its importance."

Red Cross Public Health nurses are at work today in forty-eight States, Alaska, the Virgin Islands and Porto Rico. It is a record that may well give you pride; but what is perhaps even more valuable

is the fact that there are among you many who have been glad to promote the idea and support the conception of others because they promised progress for the world. You have been an influence in stimulating the public to know that the Public Health nurse is an agent of service.

Among the speakers at Thursday afternoon mass meeting, devoted to consideration of the foreign service of the American Red Cross, which today as it regards Europe in particular is devoted to health and medical work among children, were Miss Alice Fitzgerald, director of nursing, League of Red Cross Societies; Dr. James W. Robertson, Canadian Red Cross; Dr. C.-E. A. Winslow, Yale Medical School; Hong Nien Tong, of the Chinese Embassy; Charles R. Crane, former Minister to China; and Dr. Albert Ross Hill, vice-chairman of the American Red Cross.

Miss Fitzgerald recounted her efforts to establish a standardized Public Health Nursing system in the various countries which are members of the League of Red Cross Societies, citing as her greatest obstacles in this effort as the varying standards of nursing in other countries and the geographical distances involved. Dr. Robertson discussed the health work that has been undertaken by the Canadian Red Cross.

The Ninth Crusade

"It is our hope and belief," said Dr. C.-E. A. Winslow, who was General Medical Director of the League of Red Cross Societies, "that the Red Cross Societies of all the nations will shortly be enlisted in what has been called the ninth crusade, the greatest crusade in the history of the world, a crusade which will make the twentieth century memorable as the century in which the ravages of preventable disease were at last checked and controlled through the organized efforts of all the peoples of the earth."

Dr. Hill outlined the work of the Red Cross in Europe today, of which he is director. The make-up of the child health units which the Red Cross is putting into the field, he described in detail.

The last of the mass meetings was turned to the subject of the "Red Cross Roll Call" and confidence that the American people would generously support the program of service to which the American Red Cross is dedicated was generally expressed by the speakers.

The sectional conference, embracing such subjects as "Home Hygiene

Red Cross Home Service Group, flags of the nations composing the League of Red Cross Societies, and part of the throng that watched the "Pageant of the Red Cross"

and Care of the Sick," "Nutrition Service," "Health Service," "Public Health Nursing," "Health Service and First Aid" and "Service for Ex-Service Men" aroused great interest among the delegates, for it was in these meetings that they were given great opportunity for an interchange of experiences and views relative to the best methods of applying the service of the Red Cross in their own

communities.

The Convention was brought to a close by a mammoth "Pageant of the Red Cross," in which more than three thousand persons, including a chorus of one thousand, took part. This Pageant, visually reviewing the history of the Red Cross movements, was one that will long be remembered by the thousands privileged to witness it.

of age brought by their mothers for examination; the establishment of free medical dispensaries for expectant mothers; the diffusion of knowledge relating to infant health and maternal nursing, and the supervision of boarded-out children under seven years of age.

The cost of child welfare work will be borne one-half by the state, one-fourth by the province, and one-fourth by the municipality. Provincial and municipal boards are appointed by the national board, and advisory committees are provided for.

Child Welfare in Belgium

DR. SAND gives a dramatic account of how intelligence, determination, and united effort have conspired to triumph over war, and pestilence and famine. Even during the years of occupation, when the Government had left the Belgian soil and the only central co-ordinating agency was the voluntary "*Comité National*," public health activities were started on a hitherto unknown scale, and for the first two years there was an actual decline in infant mortality, probably owing to the cessation of industrial work for women. The Children's Welfare League, which had begun to function to a limited extent before the war, developed in the midst of the most difficult circumstances until even the smallest village was reached.

In spite of these efforts the average child was, at the time of the armistice, one full year backward in normal development, the weight of the average Brussels schoolboy was three pounds below normal, and of the average schoolgirl seven pounds. The first step in the medical reconstruction of industry was the establishment of an independent labor medical service, which includes in its functions the protection of expectant and nursing working women and the care of the health of working children. The service immediately formulated a constructive program which enlisted the cooperation of all agencies concerned in the promotion of public health, including the health of working mothers and their children.

In the United States eighteen states provide for the physical examination of every child entering industry, but no state has provided for examinations of working children at regular intervals. Belgium has adopted the advanced program of a medical examination for every juvenile not later than a month after he has entered an industrial occupation, to be repeated once a year

until the child reaches eighteen, and oftener in case of disease.

Belgium has realized that health protection in the community must go hand in hand with health protection in industry, and Dr. Sand emphasizes the following points: General public health work, child welfare, housing, the restriction of alcohol consumption, and education and recreation, both for adults and children.

A national children's board has been established, which is maintained by public and private funds, and which supervises and supports child welfare organizations meeting certain conditions. The child welfare program includes the periodical free examination of children under 3 years

Health Menace In School Buildings

The third "Know and help Your Schools" report of an inquiry directed by the National Committee for Chamber of Commerce cooperation with the Public Schools and the American City Bureau is based upon replies to questionnaires sent to 375 cities. It constitutes a philippic against old school buildings whose insanitary condition and fire hazards are a serious menace to a large percentage of American school children. Nearly 88 per cent of the total outlay is for sites and new building, and a mere 1.8 per cent for the alteration and equipment of old buildings. Conditions are particularly bad in the eastern cities.

Dr. Rene Sand, professor of Industrial Medicine, University of Brussels, in discussing "Industrial Medical Reconstruction in Belgium," brings out the fact that child life was penalized by the war, necessitating a reconstructive program.

Rural Health Work by Means of Traveling Clinics

The Fixed and Inaccessible Health Center Gives Way to Flexible Methods

By JOSEPH J. WEBER, M.A., MANAGING EDITOR, THE MODERN HOSPITAL, CHICAGO, ILLINOIS

HEALTH campaigners, particularly during the past five years, have not been content solely to provide buildings, equipment and medical and surgical skill to which the sick could resort for diagnosis and treatment. Rather, they are determined to carry the gospel of good health, and in some measure the means of attaining it, direct to the people, especially to the people in rural communities, where the ways of health are not always clearly understood and where modern facilities in equipment and skilled personnel for the diagnosis and treatment of

tation with motion pictures and slides; motor trucks, as the Cleveland Children's Year Special conducted by the Children's Year Committee of the Council of Defense of Cleveland, O., in 1918, which carried exhibits, gave motion picture shows, distributed literature and conducted a dispensary for child hygiene and welfare work; the Flying Squadron of Health which by exhibits, stereopticon slides and lectures carried propaganda throughout Wisconsin from 1911 to 1915 for tuberculosis prevention and cure for the Wisconsin Anti-Tuberculosis Association; trolley cars, as the Children's

Board of Health to carry an exhibit of animal parasites and a working field laboratory. Doubtless we shall soon witness the White Winged Squadron swooping down from the great spaces above to deliver its message of health to human beings diseased either in body or mind.

Any organization contemplating using this instrument for accomplishing some of its work, particularly for publicity purposes, will find not only the health publicity campaign, but also campaigns relating to a variety of other vital subjects, rather fully discussed in Mrs. Mary Swain Rout-

The Alameda County, California, touring car is under the direction of the Tuberculosis Association. It carries particularly the message of mouth hygiene and reaches industrial groups of foreigners who face unnecessary health hazards with unenlightened self-indifference.

disease are not always readily available. This campaign has been made possible by an interesting, and often picturesque, combination of modern educational materials and methods and modern transportation facilities. In this aggressive campaign, railway trains and parts of trains have been used, as, for example, the Sanitation and Health Train which the State Board of Florida conducted during 1916 and 1917 for the purpose of delivering lectures on health and sani-

Year Special conducted in 1918 by the Women's Committee of the Michigan Division of the Council of National Defense for exhibit, examination, lecture and demonstration purposes; horse drawn vehicles, such as the Health Exhibit Wagon conducted by the Vermont State Board of Health during 1913 and used for moving pictures and health exhibits; and, deviating slightly from these types, even the house-boat "Josephine," which was chartered by the California State

zahn's book, "Traveling Publicity Campaigns," published last year as one of the Survey and Exhibit series of the Russell Sage Foundation.

Traveling clinics usually have any one of three main purposes: (1) General or specific education. (2) Examination, diagnosis, and advisory service. (3) Definite treatment.

In some instances the traveling clinics are definitely equipped to function along two of these lines, in a few instances along all three. When

treatment is given, the clinic manifestly must function, also, along diagnostic and educational lines.

The traveling clinics whose purpose is primarily educational in character have resorted to practically every known modern educational expedient, including formal lectures, informal talks, personal advice, pamphlets, leaflets, exhibits, stereopticon views and motion pictures.

One of the most interesting of these clinics is the Child Welfare Special which began its career on the 11th of July, 1919, in Morgan County, Illinois. This clinic had its origin in the need of the rural child and the desire to give the country child the health and medical facilities heretofore accessible only to the city child, and to bring home by personal contact the lessons of child conservation. Although children were examined at this clinic (100 to 150 weekly in the counties first visited), these examinations were merely incidental. The main purpose of the clinic was to demonstrate by means of the examination of the children the need of periodical medical examination and the method of meeting this need, and to stimulate and aid in the organization of permanent child welfare work in the community. The examination of each child usually took about twenty minutes. During the examination the doctor would discuss each point with the attending parent, who at its conclusion was given copies of appropriate pamphlets published by the Children's Bureau, as well as a record of the child's physical condition and any written recommendations the doctor might have to make. If any defects were found, the parents were urged to have them attended to promptly by their family physician. As the clinic was not for clinical purposes, but wholly educational in character, sick children were rejected and referred either to a physician or to another clinic.

Another interesting experiment,

which illustrates the use of the motor truck for educational purposes along health lines is the Social Hygiene Field Car. This experiment is being carried out under the auspices of the American Social Hygiene Association, the American Red Cross, and the United States Public Health Service, and state and municipal boards of health. Its purpose is to carry on an educational campaign throughout rural districts through the use of moving pictures, stereomotorgraph slides, and other exhibits, regarding the ravages of venereal diseases and methods to combat them. Special women's and men's lecture films are used for the women's and men's meetings, respectively. In this campaign, school houses, churches, lodge rooms, and other available meeting places are used for the lectures.

An interesting modification of the motor truck whose purpose is primarily educational, is the Health on Wheels Truck of the New York State Department of Health, which is especially equipped to show health films at any remote locality, whether or not suitable halls or electric current are available. The body of this truck is so designed that it can be used as a temporary infant welfare station, as a miniature traveling laboratory, as a means of transporting x-ray and other apparatus for clinical work, and for other purposes.

For the purpose of weighing and measuring children and rendering advisory service, the Public Welfare Committee of Montreal conducts a traveling baby clinic. Ordinarily, the patients are limited to twenty-four months and under. This clinic, the first of its kind in Canada, was put into the field in the autumn of 1917, and since then close upon 1,000 children have been examined. This healthmobile completed a three weeks' itinerary through rural Quebec, examining both children and babies, and conducting a public health exhibit at the rural fairs.

An illustration of the second type of clinic, that is, the clinic whose primary purpose is diagnostic rather than educational, is the occasional tuberculosis clinic which was successfully initiated by the Tuberculosis Committee of the New York State Charities Aid Association. In the work of establishing tuberculosis dispensaries in the cities of New York state, the fact was brought out that a real need of facilities for the examination of the lung existed in small communities and rural districts where there was no dispensary and often not even a resident physician with special training and experience in the diagnosis of tuberculosis, especially in its early stages. To meet this need, traveling dispensaries were established which furnished expert medical examination to remote communities at irregular and rather long intervals. They served, however, not only to furnish this much needed diagnostic service (treatment was never rendered), but also to establish the need of tuberculosis hospitals where they did not already exist, to promote the increased use of existing hospitals, and to bring to light the conditions that promoted the spread of the disease, and thereby made possible effective methods of preventing it. These clinics have grown in number until now they are held under the auspices of the New York State Department of Health and the New York State Charities Aid Association jointly and separately, and under the auspices of local communities who have established them on their own initiative.

The Health Clinic of the Chicago Tuberculosis Institute, which serves a similar purpose, works on a definite schedule, covering about forty different towns each month at specified times. In mild weather the clinics are held in the healthmobile itself; in cold weather they are held at waiting places, usually a schoolhouse or church. An average of two hours is

spent at each place, during which period from ten to fifteen patients are seen.

A so-called diagnostic traveling clinic on a somewhat more ambitious scale, though not employing a motor truck as a means of transportation, is that recently inaugurated by the New York State Department of Health. This clinic is diversified in

secretary of the Junior Red Cross, at the Chapter House. When the dentist completes his stay at a given school the executive secretary of the chapter compiles from the day sheets and cash received a statement of the work done and the financial transactions, and sends it to the principal to be countersigned. The local dentists have been very cordial and have found

suitable buildings. The purpose of these clinics was not only to teach the laws of health and assist in the improvement of local health conditions, but also in remote places to make medical inspections, treat children and those afflicted with tuberculosis, and do dental work, particularly for children and emergency cases. The main effort was directed toward impressing on people the importance of having everyone, especially the children, frequently visited by the local physician, in order that disease and effects may be dealt with in their early incipency. Only persons who were unable to pay were treated at these clinics unless a special request was made by the family physician.

Preparing for Effective Action

In most instances the motor clinic has to depend on advanced publicity and organization for real effectiveness. The kinds of advanced work needed depend, of course, upon the nature and scope of the campaign.

As indicative of the advance work required, let us consider the work done preliminary to the visit of the Child Welfare Special.

This clinic went only on the invitation of the State Board of Health, thereby insuring the cooperation of local agencies, such as the County Medical Society, the County Board of Education, the Board of Trade, women's clubs, and kindred organizations. These bodies assist in mapping

The "Child Welfare Special" is a great, gray automobile, used in educational extension work of the Children's Bureau.

character, is in session at given points for a week or more, devotes its attention to a variety of diseases, and is manned by skilled visiting specialists.

The Treatment Motor Truck Clinic

The third type of clinic is that which, while doing diagnostic work, also goes further when necessary and gives treatment as well. Obviously, the traveling treatment clinic has marked limitations. It has, however, proved a success in the treatment of teeth and trachoma, as witness the Mobile Dental Units of Nassau County, New York, conducted under the auspices of the Junior Red Cross and the Traveling Trachoma Clinic conducted by the United States Public Health Service Bureau for the purpose of operating on cases of trachoma.

The clinic visits each school upon definite written application by its superintendent. A date is fixed and when the car arrives, the equipment is carried into the school house and the examinations begin. Defects are jotted down on a mouth chart, made out in duplicate. One of these charts is retained by the chapter and the other is sent by the child to his home.

Following the noon hour of the first day, signed consent cards and money begin to come back and the dentist starts his work. A record of the work done each day is made out on the "day sheet" which is mailed by each dentist each day to the executive

that the educational work of the clinic has filled their waiting rooms.

A somewhat more ambitious scheme was the two motor clinics put into the field by the Nova Scotia Provincial Branch of the Canadian Red Cross Society. They traveled throughout the Province of Nova Scotia during the months of July and August of

The Social Hygiene Field Car carries paraphernalia for outdoor exhibits or indoor clinics. In one week in North Carolina the message so carried reached 6,100 people, most of them inaccessible by any other means.

last year. Each clinic consisted of motor trucks, motor ambulances and touring cars. These vehicles conveyed four medical specialists, dentists, trained nurses, and Red Cross representatives, and the equipment of a ten or twelve bed hospital to be set up quickly in school houses or other

out the itinerary, arranging for meetings to explain the need for vigorous manhood and womanhood, as well as the purpose of the clinic. Committees were organized in the larger towns and chairmen and hostesses in the smaller settlements. These committees were responsible for

receiving the Special and its personnel, securing publicity, an appropriate stopping place for the clinic, the attendance of special groups and the foreign born, making appointments with families desiring conferences, providing motor service for speakers, and other activities. An advance agent usually preceded the arrival of the clinic by about two weeks, and assisted in the organization of these committees and their work. This agent carried with her material for the newspapers, printed instructions for the committees, copies of announcements for the ministers and posters advertising the Special. In each community she visited the local officers, editors, physicians, ministers, farm advisers, county demonstrators, representative citizens, business men, and social agencies to explain the purpose of the clinic.

What of Results?

The specific results for each of the particular enterprises which have utilized the mobile units for the extension of their work have, on critical estimate, been highly favorable. The wake of the "Child Welfare Special" was marked by broad and lively interest in the whole subject of infant welfare. Tuberculosis work everywhere has received impetus from the traveling chest clinics. From Florida and from North Carolina, in particular, have come favorable reports of the social hygiene programs so initiated. This account is in no way to be construed as an attempt to evaluate the traveling clinic as an instrument for promoting the public health. At best, this is a difficult task, and the subject is important enough to warrant a separate paper. Whether its advantages outweigh its disadvantages when examined in relationship to particular purposes, must, until a greater volume of data is available, remain the responsibility of those in charge of particular projects.

Women in Health Service

Health News, of the Public Health Service, states that in proportion to its size the personnel of the United States Public Health Service probably includes more highly trained and specialized women than any other branch of the Federal service. Among these are the surgeons, the reconstruction aides, most of whom have had college training or its equivalent, the nurses' corps, and the special body of nurses of possibly 165, who work in clinics and miscellaneous health activities, specializing in venereal disease treatment.

Nativity and Infant Mortality

A STUDY made by P. R. Eastman in 1919 and published in the *Hospital Social Service Quarterly* attempts to bring out the racial factors involved in infant mortality. The deaths analyzed represent an infant mortality of 95.7 for each 1,000 registered births; a rate which taken in its entirety, bears, favorable comparison with not only the rest of the states of the Union, but also with most of the principal foreign nations as well.

The chief interesting feature is that the mortality of children born of native white mothers was only 87 per 1,000 births; whereas, that of the foreignborn mother's children was 108.4—the high rate among the foreign-born element being due principally to a group comprised of Russian, Poles, Austro-Hungarians, and Italians, whose collective rate was 109.5. The rate among the children of Austro-Hungarian mothers was 129.6, Poles (including those from Germany, Austria and Russian Poland) 122.7, British 71.7 and Irish 96.9.

The mortality under one year of age was much higher among babies of the foreign-born mothers than among those of native mothers, the death rate at the age of one week was considerably greater among the native (35.2) than among the foreign-born group (30.3), with the difference much enhanced for the Russian, etc., group (26.6). At the age of one month, the infant mortality of the native element was still highest, the rates being: Native 42.7; total foreign, 45.2; and the Russian, Poles, etc., 42.7; but at three months of age, there was very little variation between the rates of the three classes.

Contrasts Offered

Of the total number of deaths which occurred at the age of one week, 50.4 per cent were stated as due to premature birth, 12.8 per cent to congenital malformations, 6.2 per cent to congenital debility, and 13.5 per cent to injuries at birth. During the age period from three months to one year, these causes accounted for only 7.2 per cent of the total deaths, the principal causes being given as the respiratory diseases, which resulted in 24.7 per cent, and the gastro-intestinal diseases resulting in 41.3.

It is therefore assumed that the principal causes of infant mortality incident to the native population are

those due to prenatal influences and to injuries at birth, while among the foreign element the diseases of the respiratory and gastro-intestinal tracts are the predominant causes.

The mortality from prematurity, etc., of infants of native mothers was 45.3, whereas, the rate among those of foreign-born was only 37.7, and that of the group comprising the Italians, Russians, etc., only 35.

Since the particular causes of infant mortality are materially influenced by national and racial traits and customs, more careful consideration of the character and habits of the populations is essential to any substantial progress in the improvement of child welfare in the future.

When starting a campaign to reduce the infant mortality of a community, a careful survey of the nativity, character, customs, and habits of the people should be the first consideration. Upon the result of this survey the whole future course of the campaign should be outlined. If it is learned that the community is of native stock, a course of instruction in prenatal care probably will be found most advisable; if the population is predominantly of foreign birth, then a campaign of education relating to the improvement of sanitation and to proper infant feeding will be likely to result most satisfactorily.

English Research in Radio-therapeutics

The British Association of Radiology and Physiotherapy has placed the sum of twenty thousand dollars to the purpose of studying claims made by the new intensive x-ray treatment of cancer. The study may be extended to other subjects later held to be necessary to understand the cancer problem from any point of view that may arise. To initiate the study a scholar, on a salary for two years, will proceed to Erlangen, in Bavaria, where this treatment has been elaborated for a number of years. If his survey of the work is favorable, a complete outfit of the apparatus, such as is used at Erlangen, will be ordered forthwith and installed at the Manchester Royal Infirmary, where research will be undertaken along the lines indicated in his preliminary report. Collaboration will be undertaken with other specialists when the report of the scholar is received and work is about to commence at the Manchester Royal Infirmary.

A Contribution of Biometry to Philosophy

THERE are few more stimulating minds in the field of modern public health than that which directs the activities of the Department of Biometry and Vital Statistics in the School of Hygiene at Baltimore, and the group of contributions which has recently been distributed from Dr. Pearl's laboratory is rich in value and suggestiveness. Modern methods in handling hospital statistics,¹ a plea for the use of mechanical tabulating systems should be studied by all who are interested in the use of the hospital as a laboratory of scientific research. The second group of Dr. Pearl's influenza studies² furnishes an admirably thorough analysis of the factors correlated with the explosiveness and destructiveness of the influenza epidemic in 1918 in different cities. The more complete studies here reported remove any lingering doubts left by the author's previous paper and make it abundantly clear that neither age or sex, distribution of population, density of population, longitude, or rate of growth of the population bore any significant relation to either the explosiveness or the destructiveness of the disease. Latitude did show a suggestive correlation, the severity of the disease increasing as one passed southward. Both explosiveness and destructiveness on the other hand were definitely and strikingly correlated with the normal death rate from all causes and with the normal death rate from organic diseases of the

heart during preceding years, while explosiveness but not destructiveness was correlated with the normal death rate from pulmonary tuberculosis. This is a conclusion of the first importance and represents a substantial contribution to epidemiology. Another of Dr. Pearl's papers in which the public health worker will be particularly interested is the study of infant mortality³ in which the author divides the causes of infant mortality into two groups, those which are now in the way of being directly controlled and those which are not practically controlled to any considerable extent and shows that while the latter group are reasonably consistent in their incidence in various cities the diseases of the controllable group exhibit the most significant and marked variation, forming, as the author says, "a real justification of the faith that is in the public health officer of vision."

In a remarkable series of essays on the biology of death⁴ Dr. Pearl contributes one of the most suggestive contributions to biological philosophy that has appeared in recent years. By a thoughtful analysis of phenomena of life and death in protozoa and metazoa and particularly of the results obtained through the Harrison method of cell cultivation, he concludes that "it is the differentiation and specialization of function of the mutually dependent aggregate of the cells and tissues which constitutes the metazoan body which brings about death, and not any inherent or inevitable mortal process in the individual cells themselves." He then proceeds to discuss the statistical facts in regard to human mortality as evidenced in life tables from ancient Egypt and Rome to the present day and shows how the two factors of inherited constitution and environmental control through sanitation have operated throughout the ages. He next examines the causes of death, classified in the interesting way which he suggested in an earlier paper, according to the particular organ systems affected, and by a comparison of mortality tables in organisms as widely separated as man and the fruit fly, emphasizes the importance of the hereditary factors which govern the span of life. We may feel that certain of his criticisms of the claims for environmental sanitation go further than is justified but it is certainly well that public health workers should recognize clearly, and appreciate justly, the fundamental biological limitations within which their activities must operate. The conclusion that the time relations of the life span is immediately determined by the way potentially

mortal cells are put together in mutually dependent organ systems and that this mutual fitting together of the organs is determined by heredity seems thoroughly justified by the evidence presented; while the third general conclusion suggested by Dr. Pearl that environmental circumstances play their part in determining the duration of life by influencing the rate at which the vital patrimony is spent is a speculation of the greatest theoretical interest.

Factors Accounting for the Increasing Life Span

DATA presented to the Section on Preventive Medicine and Industrial Diseases by Capt. W. E. Elliott, at the last meeting of the British Medical Association, show that in the decade 1871-1880 the expectation of life in Great Britain was 41.0 years. In the decade 1911-1920 it was 51.5. In other words, the average life span has increased eleven and a half years in half a century. This increase in the average life span is due to the years saved in the younger and more productive decades and may be accounted for by the reduction of typhoid and the water borne diseases, the elimination of typhus, and the more general improvement of the environment, particularly that of childhood. In spite of the fact that the population of Great Britain is 13,000,000 greater than it was in 1871, there are 50,000 less deaths per annum. In 1854 the death rate was 37.2 per one thousand; in 1920 it was 12.4 per thousand.

One is led to speculate on the future increased average span of life. Projected curves are tricky things and Hosea Bigelow's dictum "never prophesy unless you know" still holds, but if it were not for the human proclivity to guess, Wall Street and the race tracks would have to go out of business. It is scarcely to be expected that the rising curve will be able to hold its own during the decade of post-bellum readjustment; in fact, it is doubtful if it will pass its present mark until the period 1941-50. Bearing these facts in mind, and the difficulty in increasing the life expectancy in the upper age groups—the expectation for an Englishman of 70 is now 13 years, the same as in 1871—the following table has been prepared:

EXPECTATION OF LIFE, GREAT BRITAIN

1871-1880	41.0	1941-1950*	52.8
1881-1896	43.7	1951-1960*	53.9
1891-1900	44.1	1961-1970*	54.5
1901-1910	43.9	1971-1980*	55.5
1911-1920	51.5	1981-1990*	56.5
1921-1930*	50.4	1991-2000*	57.4
1931-1940*	51.4		

*Estimated.

The increasing expectancy in the past is explained in part by the fact that in Great Britain the average number of deaths per annum from typhoid fever in the period 1871-1880 was 7,800, while in 1920 it was 537; in 1870 the scarlet fever deaths were about thirty thousand, in 1920 about one thousand; while in the past decade the annual number of deaths from pulmonary tuberculosis has fallen about six thousand. Among the communicable diseases, measles, whooping cough, influenza, poliomyelitis, and cerebrospinal meningitis still require the evolution of adequate control measures. The campaign against venereal diseases is bearing fruit and will undoubtedly do much to increase the average length of life in the middle age periods, as will also the movement for the control of cancer. Industrial medicine, mental hygiene, and the maternity and child welfare work will cause a continuous diminution in the mortality rates, while an increase of medical knowledge will do much to decrease the death rate from the so-called constitutional diseases.

Thus the achievements of the past raise bright hopes for the future. The health idea is becoming the universal custom of life—a custom based on knowledge which is becoming widely diffused throughout the general public.

Needless Noise the Proper Concern of Health Officials

THE serious consideration of the deleterious effects of noise upon the public health is something which should have been undertaken long ago. Boiler makers' deafness is a recognized ailment, yet the thousand and one auditory and nervous disturbances of a minor character are rarely attributed to the well nigh continuous din and clatter of cities. The hubbub of the crowded street, the groaning of metal tires upon pavements, the snorts of trucks, the grinding of the elevated, the shouts of newsboys and hucksters, and all the other useless, yet none the less diabolical noises require the elaboration of a special repressive complex, an environmental adaptability which it is not always easy to achieve. The full bosomed contralto who rends the evening air, the razor-edge tenor which is scratched from a plate of denatured rubber, the mechanical piano, the fiend who practises on a saxophone, are as nerve racking and unnecessary as the early morning street car gongs, the bellowing locomotive whistle, and the automobile horn screeching for a best girl to hurry.

These sounds constitute an intrusion on connected thought. The mind is torn between the reception of auditory stimuli and concentration. There naturally follow resentment, irritation, and

the repression of the desire to slay the trombonist across the street who is blaring "The End of a Perfect Day," off key.

The real psychological explanation, though, lies in the knowledge of the utter uselessness of most of our city noises. Noise spells wasted power. It is a vestigial remnant of barbarism, made more effective by invention. What is the need for gongs in a world where everybody has a timepiece and most of our activities run on schedule like a railway? The men of the A. E. F. learned from the tiny whistles of the French locomotives how unnecessary is the brazen bellowing of the prairie whistle which tears across the silence of four miles of growing corn and starts the drowsy rustic to his milking. The muffler which can't be cut out has come to stay and, while of course nothing short of extermination will silence the cracked soprano, the raucous junk collector, and the cheerful idiot who plays one-finger piano solos, may blessings be upon the head of the health officer who will recognize and treat unnecessary and avoidable noise as a nuisance and a menace to the public health. And this is logical, for surely an offense to the ear is quite as bad as an offense to the eye or the nostril—perhaps it may be even more harmful—and surely the commission of the one should be as punishable as the other. The blessed contentment of the quiet of the open fields is not imaginary, it is the sigh of relief from nerves too taut from the stentorian voice of the city and, while the beatific silence may be occasionally broken by the tinny cacophony of a senile vehicle from Detroit, the sound-tortured soul is soon assuaged by Nature's silence.

Mutabilis Semper

IN ALL probability, about the time that Eve's granddaughters began going out to campfire dances with their cousins, their mothers used to foregather on the side line and decry the immodest tendency of modern dress, recalling those good old days when the truly modest virgin never appeared save in the largest fig leaves locally obtainable and no indecent huzzy enticed an innocent son of the house of Abel by the bobbing of her hair. And so it has continued even unto now.

The history of the world might be written round the perennial discussion of dress reform and the protest of the older generation against departures from established sartorial standards.

Yet dress reform, as such, has gotten nowhere. The ardent, goggle-eyed, short-haired woman in "sensible" clothes and square toed shoes never made a dent on that arch-producer of breast cancer, the old fashioned corset. Can anyone ever forget that rugged, ribbed monstrosity which

incased our modest grandmothers from manubrium to symphysis? Yet that steel-proof cuirass, guaranteed to withstand the most ursine embrace, has given way before the subtle hand of fashion and now the fireside tabbies are having conversational convulsions over the fact that at terpsichorean entertainments the modern girl either parks her stays or merges into the mural decorations.

Forsook, why not? The girl is going to indulge in the rhythmic exercises of the syncopated toddle and the muscles of the abdominal girdle are a great deal better off unhampered. If one compares the modern figure with the ant-like silhouette of the early Grover Cleveland period, one cannot but be impressed with the very genuine reform which has occurred and now that women are learning the joy of stayless exercise, there is a hope that corsets will become as extinct as bustles and the prevalence of enteroptosis correspondingly decreased.

A corsetless age would mean greater attention to diet—for adiposity would then mean social oblivion—and the stimulation of exercise to maintain the natural figure. These are accomplishments which direct dress reform never could have brought about any more than it could abolish the voluminous, heel-flapping, dust-collecting, step-impeding skirt. What a hue and cry there was when the hoop skirt, which occupied twenty-eight square feet of floor space, was abandoned by the graceless post-bellum vampires; but consider the shock which the knee skirt and rolled down stocking of mode would have produced. Peradventure yes!

If the woman who did her courting in seven ruffled underskirts and a set of ribbed nether garments which enveloped her from vertebra prominens to tendo achillis, not to speak of a considerable exterior array of uncompromising light-proof garments, was to take one glance at the up-to-the-minute girl whose raiment is a negative pressure above the xiphoid cartilage and below the patella, resuscitation would not occur. But which of the two will history say wore the more sensible dress? And are not these abbreviations hygienic, are they not a distinct advance toward a real improvement in dress?

"A woman's hair is her glory," but on the other hand in the days when a woman must have a hirsute decoration, natural or otherwise, it was a never ending bother and inconvenience, until the movies demonstrated how much better it looks bobbed. Anyone who is familiar with fermented scalps or with the fauna of the longhaired can understand what a blessed relief it must be to wash it under the shower without having to sit

on a sunshiny back porch all morning. Yet some strait-laced people say that the girl who goes without stays and hirsute ear-muffs must of necessity be a wanton and a menace to public morals. Pish and again tush! There is no more reason why bobbing the hair should make a girl a sink of depravity than that an A. E. F. haircut should make a boy a bank robber.

Yes, these are advances, advances toward health, toward sanity and, whether we rail or not, these advances will continue. Fashion, after all, is a dress reformer and since it reflects the sentiment of the age and this is the age of public health, it may be expected to fit its output more accurately to the sanitary model.

As far as our morals are concerned it may be pointed out that they are improving slightly in spite of never ending dress mutations and the assaults of the rouge pot and the powder puff and, after all, a woman's shoulder or knee are no more basically immoral than the end of her nose or the distal phalanx of her thumb.

The White Woman and the Tropics

THERE is a widespread belief, even among medical men, that there is something peculiar about the tropics which rapidly undermines the health of white women. This mysterious something is supposed to manifest itself particularly at the menstrual epoch; white women are supposed to retrograde morally and dispositionally under its malign influence; neurasthenia, hypochondriasis, and insanity are supposed to dog its trail.

All of this has been blamed on continuous high temperatures, white light, humidity, and the combination of all three. Strangely enough, the baleful manifestations of this tropical *ignis fatuus* are observed in humid and dry, cloudy and bright, sea level and mountain, hot and cool tropics—and curiously too, there are many white women who emigrate to the tropics from the temperate zone and live for years at the equator without displaying any of these weird symptoms. Taken by and large, white women of the same general habits have about the same degree of health no matter what their exact geographical position. To be sure, no sensible woman dresses, eats, and exercises in exactly the same way in Curacao and Chicago; but the same general habits would fit Managua quite as well as Memphis, because leaving out of question, the communicable diseases, personal health in the tropics is largely a question of cleanliness, diet, and exercise.

Cleanliness is absolutely necessary if one is to live in comfort to himself and his associates. This

is particularly true in the humid tropics because there the opportunities for the proliferation of skin bacteria and fungi are almost ideal and, in the absence of at least one daily soap and water bath, putrefactive and infectious skin processes are almost inevitable. Cleanliness of this sort is so imperative that in many places the whites, both male and female, have adopted axillary shaving as a routine practice. As a corollary to bodily cleanliness, the sterilization of clothing is a *sine qua non* if one is to avoid the various forms of ring worm and other parasitic fungi. The necessity for oral cleanliness is then about the same as in the temperate zone.

Diet is largely a matter of personal taste but as a rule it is wise to adopt the local dietary, bearing in mind the fact that carbohydrate poisoning is very common in the tropics. The candy box, the rich after dinner "dulce," the avoidance of roughage, all contribute to this. "Tin canitis" is largely the very human revolt against the same old tinned asparagus, and the inevitable canned peach.

Alcohol must be taken only in extreme moderation and in the absence of daily exercise, never. The tropical steady drinker who does not exercise, rapidly drifts into the class which has "missed too many boats" and breaks up quickly. There is a lure about all exotic places which is apt to translate itself into a lessening of self-restraint. As a matter of fact though, white women are just as sound mentally and morally in the tropics as anywhere else since unrestrained men and women do silly things all round the globe in exact proportion to the social, not the geographic, degree of latitude.

Exercise in the open air is even more needed in the tropics than in cooler climates. The daily siesta, the easy chair, and the avoidance of walking are deadly in warm countries and a great many of the so-called tropical neurasthenias are merely the results of physical laziness. One reason why women are so much more apt to break under the strain of tropical life is the fact that they take practically all their exercise at the bridge table and the afternoon tea. Conversely, tennis and golf, particularly the latter, are tremendous health adjuvants in warm countries. These same outdoor games do much to prevent those mental quirks which inevitably arise when a small isolated community of white women are made absolutely dependent on one another's society, while from the moral viewpoint, they stave off a world of entanglements. Of course, one dresses for comfort and sun protection, but, given half a chance, the white skin develops a pigmentary armor against white light which, while not approved by beauty parlors, is quite effective.

Golf is making the pink and white woman a thing of the tropical past and the seal brown freckle is now to the social fore "on the lap of the line." As a former beauty once said, "Well, I'm freckled like a guinea but thank God, I've my health."

American Public Health Association Meets

ONE way to make health interesting is to bring together from the four corners of the Country—as was done on the occasion of the Semi-centennial of the American Public Health Association in conference at this writing—representative health workers with illuminative accounts of the health work being carried on in their respective districts. Another is to make a popular dramatic appeal through the presentation of methods of health work, so fully exemplified in the health exhibit conducted during this conference for the purpose of stimulating workers and to raise the standards of health improving plans. Another is specific training for health apostles, and such opportunity as was afforded by the Health Institute to demonstrate in actual operation proved methods applicable to various phases of public health activities. Health leadership is ours if we choose to accept it and fit ourselves for the responsibility. The achievements of fifty years give us hope; failures and inadequacies of health service direct future enterprise. The inspirational benefit of the biggest and best public health meeting ever held by the American Public Health Association will soon be made effective throughout the Country by the more than five thousand delegates attending the conference.

The Complex Physiological Action of Sunlight

RECENT investigations in regard to the effect of actinic rays upon rickets furnish another instance of the tendency of science to vindicate the common instincts of mankind. A belief in the therapeutic and curative influence of sunlight has been stronger in popular than in scientific circles and the critical investigator of physiological problems has cherished a certain skepticism in regard to such an influence and has been inclined to attribute the beneficial effects of exposure to sunlight to accompanying influences of temperature and air movement of a more readily comprehensible nature. The work of Huldshinsky¹ and his associates in Germany seems however to have given convincing evidence that rickets can actually be cured by treatment, not

only with sunlight but with ultra-violet rays, the influence of other factors being apparently completely excluded in the latter case. Hess, who reported unfavorably on this treatment in an earlier paper,² has now repeated his work with favorable results,³ and E. A. Park, at a meeting of the Society for Experimental Biology and Medicine on October 19, also reports definitely encouraging results. The physiological reactions involved remain exceedingly obscure. We have a disease which appears to be fundamentally due to an unbalanced relation of mineral salts in the organism, whose manifestations can be abolished on the one hand by the administration of cod liver oil and on the other hand by the effect of actinic rays upon the skin, a complex relationship which opens up large possibilities of speculation and research. The main facts however seem to be well established and the entire question of the effect of sunlight on physiological reactions must be reconsidered in the light of such findings.

CONCRETE and convincing evidence of the value of health educational and medical service is afforded by the figures just available on the campaign of the Metropolitan Life Insurance Company, instituted in 1910, with the object of reducing the death rate among insured wage earners. From year to year the program was extended until it now reaches in excess of thirteen million men, women, and children of the wage working population. It is reported that in the group served in 1920 there occurred thirty-eight thousand fewer deaths than would have been the case if the 1911 mortality rate had obtained, and that the average life expectancy of white males at age ten was increased in the same period from 45.6 years to 49.5 years, which means a clear gain of nearly four years for every white male. There is no record, says the report, of a like increase in the life span, within so short a period, in the whole literature of public health work.

CALIFORNIA physicians are somewhat progressive in their approval of the organization of physiotherapists, physiotherapy being defined by the California State Medical Society as a "group of physical therapeutic procedures to be prescribed by doctors of medicine and administered under the physician's direction by specially educated and trained technical assistants." The organization as promulgated and as now functioning is an effective unit of the medical profession of California.

The Practitioner and the Industrial Physician*

Cooperation Benefits Both Groups, at the Same
Time Serving the Best Interests of the Patient

By CHARLES EDWARD MONGAN, M.D., SOMERVILLE, MASS.

THE advent of the industrial physician whose particular work is the care of accidents and sickness in industrial organizations, the entrance of the state as a factor in the practice of medicine under the guise of the Workingmen's Compensation Law, and the insurance carriers who distribute the compensation for sickness and injury in industry have brought three new factors in recent years into the practice of medicine. To prevent waste of man power, to maintain production without serious interruption in the factory by eliminating waste of man power caused by sickness or injury, is the reason for the industrial physician. That the state should compel industry to bear in part the burden of sickness or injury by passing Workingmen's Compensation Laws is a sign of the interest of the state in the social welfare of employees. Heretofore, medicine and surgery had been the particular and peculiar functions of the practising surgeon and physician. His work was among individuals. To the individual he looked for his reward. To restore the individual to health was his sole object as physician. Industry or the state did not enter in any way in the functioning of the physician under the old régime.

Thus it happened by long custom and usage, the physician assumed that

The Industrial Board is responsible for the administration of compensation laws, but their effectiveness largely hinges upon the physician, whose function is to cure, but who has not been trained to adjudicate cases. A perfectly functioning working agreement between the private practitioner, the industrial physician, and the medical representative of insurance interests is yet to be reached, but a new ethics will evolve out of precedents established and out of a better understanding of the intent of the law on the part of both the profession and the public.

he had certain rights and duties in the community. These so-called community rights had been recognized and in a manner approved by the community. The private physician, after a course of study prescribed by a reputable medical school, had been given by these medical schools a degree which gave the possessor the authority to practise medicine. After a while the state began to take an interest in the practice of medicine and soon demanded that, in addition to the degree of M.D. conferred by a medical school, such person should also take an examination prescribed and held under the supervision of

examiners appointed by the state. After successfully passing such a state examination, he was entitled to practise medicine in Massachusetts. It was a right given to the medical man to practise his profession without restriction or without hindrance among the people of this particular commonwealth after he had satisfied the state authorities of his competency.

That was the custom until 1912 in Massachusetts, and during these years previous to 1912, by graduating from schools of medicine, by passing state board examinations, the physician acquired what is best called, perhaps, community rights. In 1912, the first Workingmen's Compensation Law was passed in Massachusetts and, unfortunately, in this law the individual was denied the right he had theretofore possessed always in Massachusetts to select his own doctor to treat sickness or to repair injury. The insurers under the Workmen's Compensation Law maintained that it was the right and the privilege of the insurers to employ medical aid and nursing care whenever that was necessary or wherever it came within the scope of the law.

Social legislation was something new to the average medical practitioner previous to 1912. In a vague and indefinite manner, he had heard something about so-called social legislation, but it was not until the passage of compensation laws that the

*Read before the ninth annual meeting of the American Association of Industrial Physicians and Surgeons, Boston, Mass., June, 1921.

physician was forced out of his isolation and unwittingly made an active functioning power of our social fabric. Suddenly it appeared to him that our modern life, with all its complexities and perplexities, had become so interwoven with the practice of medicine that for the carrying out of its functions, whether those functions were in the great undertakings of peace or the formidable work of modern warfare, the medical man stood equal and pre-eminent with the captain of industry or the commanding general.

To evolve out of these new alignments of medical practice a working scheme wherein the rights of the workman, of the employer, and the physician will be safeguarded is the aim of men interested in the new conditions that have come into our profession. The industrial physician and surgeon has, therefore, a complicated problem to solve. The industrial physician has an economic status, and he has a medical status. On the economic side, he works temporarily for industry. On the medical side, he is a physician, and in caring for the sick or injured man he will be actuated by those influences which always actuated him in treating the sick—the will to give the best possible care which may most quickly restore the sick or injured man to health. It may be also said that this is the viewpoint of the manufacturer, but the manufacturer has looked upon the sick man not so much as a patient as an economic factor in production. This fact is well known and any experience in industrial medicine will prove that the manufacturer many times looks upon the sick and the injured in industry as an economic waste or loss of man power, and he looks also upon the voluntary absence from work almost in the same light as the involuntary absence from work, for both mean waste and loss and, in some highly organized industrial organizations, a disturbing element in production.

Difficulties Ensurue

To take away from individual workmen the right to employ his own physician when injured or sick, no matter when or where, caused a great deal of resentment, not only on the part of the physician but also on the part of the workman. The physician considered that his community rights had been interfered with,—a right that custom had been made in Massachusetts almost equal to law. The workman became suspicious and looked with askance on any service given to

him by the industrial surgeon or by the surgeon or physician offered by the insurer and in this way the industrial representative. No matter how well equipped or how competent the physician representing industry might be, he did not seem to satisfy the injured workman. Here comes in that personal element which exists between the patient and the physician and which plays a vital part in the practice of medicine. That vague and indefinite condition which is expressed oftentimes by the phrase "the human element."

To provide the injured man with medical service without consulting him as part of the routine of industry carried with it the idea of cold materialistic efficiency, and the implication of an effort to trample the rights and privileges of the American citizen by compelling him to take something for which he had not asked. Perhaps there was a good deal of sentiment in this mental attitude. Perhaps this opposition was founded more on fancy than on fact. However, it existed, and straightway means were taken and the law in Massachusetts was changed so that now the employee injured in industry has the right of free choice of his physician. Perhaps you may ask, is this free choice always exercised? As far as I can ascertain, many workmen who are injured seldom exercise that right. Whether they know they have the privilege or not, I do not know, but as the workings of the laws of compensation have become more familiar, I think most injured persons are willing to accept competent medical care and treatment.

In the large industrial organizations which employ thousands of men, competent medical care and treatment is at hand and is humanely given and given quickly, and I think the advantage of adequate treatment quickly given near the scene of accident gives the injured person immeasurably better chances of recovery than if treatment were delayed.

What should be the relations between the physician in industry and the private practitioner? The private practitioner asks only that his so-called community rights be observed. He looks with suspicion on the full time medical man of industry. He thinks that the scope of the industrial physician is limited to those accidents and injuries which, on account of the gravity of their nature, should be treated perhaps by the man who first saw them and had given them the first treatment, rather than

that the industrial surgeon should try to enlarge his scope of practice by treating the families of the injured who under other circumstances would not have called him.

The private practitioner naturally selects a place where he thinks he can serve the community. His calling is not commercial. It is not a business, although one of the large public service companies in Massachusetts has been lately trying to prove to a state board that the physician is in business and not in a profession. But some of us cling to the old idea that the private practitioner still serves the community which he has selected for the scenes of his activities and, no matter what his reward and recompense may be, he still serves and does not ask for a return for his services on any commercial basis. Now how can these relations be adjusted so that both the industrial physician and the private practitioner may serve the sick and serve it in a spirit of cooperation?

Effect a Compromise

In Massachusetts we have tried to solve this perplexing problem, which varies almost as much as human nature varies in individuals. It became very evident during the first years of the existence of the law that the board should have a medical advisor, and Dr. Francis D. Donoghue of Boston was selected as the man, and under his wise and discreet guidance the medical profession in its relations with industrial accidents has been most fairly treated. In Massachusetts there is what is called a Medical Advisory Committee, which has no legal status but acts as an advisory committee to the Industrial Accident Board. This Advisory Committee represents the two leading medical societies in the state. In their advisory capacity, they are called upon oftentimes to give of their knowledge and experience such advice as will enable the Industrial Accident Board to treat fairly the injured person and equally industry, as it is represented in the insurers.

Like all human agents, the Advisory Committee has not been able to satisfy all the physicians, all the injured, and all the insurance companies, but in a report to the profession which was issued June 2, 1921, is a résumé of some of the matters that the Advisory Committee has considered concerning workmen's compensation. Although this Advisory Committee has not a legal status, the Industrial Accident Board has always been ready to consider any advice it

may give. We think that the spirit that the Advisory Committee exhibited in this connection is most excellent. That the Industrial Accident Board is ready to accept, to listen, and in many cases beguiled by the Advisory Committee, speaks well for the earnestness and broadness of the Board in trying to arrive at fair conclusions.

If I may pause for a moment to become personal, may I pay a personal tribute to the wisdom, the discretion, and the indefatigable work of the Medical Advisor of the Board, for, in addition to these qualities, he seemed to recognize in this matter what few public officials recognize, namely, the human element that enters into the discussion of these cases. In this report the Advisory Committee has not attempted to lay down any hard or fast rules.

As a member of the Medical Advisory Committee of the Industrial Accident Board, I feel justified in quoting at some length from the report that has just been made to the profession. This report is remarkable, not for what it has recommended, but for what it has not recommended. To the Industrial Accident Board concerning the relations of doctors to the insurers, it has not recommended any fee-table. It has not interfered in any way with any contracts that may exist between doctors and insurance companies in taking care of cases within the legal limited time. It has made no recommendations, suggested any rate of compensation, nor has it interfered with the contracts as to special cases made outside the limited time. No rule has been made that would interfere with any contract that is expressed or implied for the treatment of any private patient. In cases in which a special private physician afterwards is called to the injured, no ruling has been suggested by the Committee to follow the settlement on an industrial rate basis. It is only that the insurer is not expected to pay more than an industrial rate. In Massachusetts the industrial rate has come to mean a reasonable fee. A ruling recommended by the Board in January, 1914, and enacted into law in the same year, provides that unusual cases are to be cared for and proper charges paid by the insurance companies beyond the two weeks limit. This was intended to prevent the possible neglect of serious cases. Of course, there may arise some difference of opinion as to what constitutes an unusual case, but when a case is reported to the Industrial Ac-

cident Board within two weeks, a satisfactory arrangement is made.

Hospital fees have given rise to a great deal of discussion. As a rule the regular established fee that is charged to the ordinary patient has been adopted by the Industrial Accident Board. In some cases the fee given the hospital is lower than that paid by others for the same treatment in that particular hospital. In some cases this may be a hardship, but in the general run of cases the hospital is satisfied with the amount given. Sometimes serious accidents call for private rooms, special nursing, and other changes which serious cases oftentimes demand, but if these changes do not include luxuries, and if the necessity of the case demands that extra nursing, extra medical care, and private rooms, these are generally allowed after consideration by the Industrial Accident Board.

A Discussion of Fees

Fees to hospitals and physicians have been a subject which has given rise to quite a little discussion and a discussion which has been carried on with more or less bitter feeling. Although I myself have not fully made up my mind as to the disposition of this item, the majority of the Advisory Committee feel that if an industrial accident patient comes to the hospital and occupies a ward bed that he is entitled to the same treatment as his next neighbor in the hospital who is not an industrial accident case, and for the service rendered to both the attending physician should receive no fee. It has been contended that as a member of the community, the industrial accident patient has the same rights in a semi-public or public hospital as a patient who was not an industrial accident case. These so-called community rights could not be taken away from him on account of his being on compensation. It is contended also by some that the community rights do not apply to an industrial accident case brought to the hospital, because the state has made special compensation laws for that case, and these laws supersede or nullify, or wipe out any of the so-called community rights that the industrial accident patient may have had.

It is contended that the physician when he took his place on a hospital staff took it with the understanding that he would give free service to all patients in the public ward and that the physician thus working in the ward receives no actual fee, but, through his connection with the hos-

pital, attains some prominence in his community, skill in treating a large number of patients, and familiarity with the methods of practice, and that his return was a large private practice by which he could give to those who could afford it, the benefit of the skill and knowledge that he had acquired in the hospital and which he freely gave to the ward patients.

I am not prepared to state which side has the better of the argument, but I will say this: I think that the private physician treating industrial accident cases in the wards of the hospital theoretically at least should receive a fee. But, owing to the conditions which prevail in very large hospitals, and owing to the local conditions that prevail in a great many cities where there are large hospitals, it has been impossible to make a plan or ruling by which the physician should be paid and justice done to the hospital and to the insurance company, and to the community. Until such a plan has been evolved, the Committee feels that no physician's fee should be charged for industrial accident cases which come to the public hospital ward.

Specialists' fees, when specialists are called in on account of their standing and reputation in the medical community, and the nature of the case justifies their being called, have always been justly considered and paid, but no actual ruling to this effect exists.

These are some of the problems that have come under the consideration of the Advisory Committee. I think, as time goes on and physicians become more familiar with the law and insurers become more reasonable in their methods of procedure when dealing with the physicians and the insured, a working basis can be supplied which will be fair to the injured, the insurer, and the doctor. A great deal of friction has been caused and a great deal of unnecessary bother has been created oftentimes by the type of man that some insurance companies select as their representatives. Some of these agents of insurance companies use manners, to say the least, that would not be tolerated in ordinary polite society. As a rule the physician is an honest man and does not start out, as the actions of some of these agents would imply, to make all he can financially out of the case. I am fully aware of the amount of tact, diplomacy, and discretion that is necessary on the part of the insurance agent, but many times we are forced to the belief that the insurance agents possess none of

these qualities or characteristics. It may be because he has been brought up commercially. It may be that his superior is constantly insisting that things should be done as cheaply as possible and that the overhead must be kept down, but it strikes me that, if physicians could be employed in disputed cases to talk with the physician whose case is in dispute, all disputed cases could be settled more quickly and more amicably. I also feel that the financial outlay caused by the employment of physicians would be more than compensated by their results.

Objectives in Common

To sum up the industrial medical man, the insurance doctor, and the private practitioner have one object in view—the restoration to health of the injured or sick person. It should be always kept in mind that the law for workmen's compensation was primarily passed for the purpose of aiding the injured man. It was not passed in the interest of the physicians. The physician is, of course, an incident in this matter. On the other hand, the law cannot be met with any degree of success unless it has the goodwill and the support of the

profession, and there is not any reason why that goodwill and support cannot be obtained. The law is not a doctor's compensation, it is a workman's compensation. The private practitioner feels that the industrial physician should, as far as possible, consistent with the safety of the patient, confine his work within the walls of the factory, for fear that the growth and development of the industrial physician will be only a matter of time when the industrial physician in some communities, at least, would control all the practice and in a small way we might develop a species of state medicine such as existed in Russia before the war, when all kinds of hospitals were connected with factories, even obstetric hospitals, and where the practice outside of state control practitioners was at a very low ebb. Visitors from the United States found some things in the state medicine of Russia to practise.

The education of the medical men in the matter of workingmen's compensation law is imperative. Before blaming in any way the Industrial Accident Board as they exist in this country, and before criticising suggestions that the Medical Advisory Com-

mittee may have given, it is well fully to consider all the factors in the case and also to study the law, and to study it thoroughly, and to bear in mind that boards and advisory committees are not responsible for the law, that the Industrial Accident Board is simply responsible for its administration.

By educating the public—I mean the medical public—I think it would be advisable to publish reports of cases that come before the Industrial Board for disposition. I think it would be well also to publish cases where there have been unusual injuries. I mean that the medical side of these cases should be published, the length of time that the patient was under medical care, and the cost. It has oftentimes been said that the responsibility of office and the assumption of responsibilities, whether they are private or public will oftentimes soften criticism and dampen the ardor of the reformer. Therefore, medical publicity in order to stimulate a deeper interest of the physician would do a great deal to help to make the compensation law what it was intended for—the alleviation of suffering and the restoration to health of the sick and injured in industry.

Defects Affecting Fifteen Hundred Men*

By B. FRANKLIN BUZBY, A.B., M.D., PHILADELPHIA, PA.

THE question of what to do with physical defectives in industry is an unsettled one and, while the number of examinations reported in this paper is comparatively small, the disposition of the partially unfit would be applicable to other plants, whether large or small.

The work reported was done at the plants of the Keystone Leather Company and the Joseph Campbell Company, both in Camden, N. J., so that the labor supply is the same in both cases. All the subjects examined were male and all received the same examination with the exception that in one-third, five hundred in number, urinalysis also was done. The type of men being practically the same at both places, even this small number in part at least, will afford an index as to the incidence of renal disorders in workmen.

A word about the completeness of the examination might be in place in

the beginning. All clothing, including shoes and stockings, was removed, and the men were examined alone in the examining room. Each examination consumed about twelve minutes and included a short history concerning previous and present occupation, age, marital condition, past illnesses, accidents or operations, venereal infections, and specifically, concerning convulsions or frequent fainting spells. Then a general inspection was made of the eyes, ears, nose, throat, teeth, body, extremities and arms. This was followed by measuring of height and weight and a testing of joint and muscle mobility and examination for hernia. There followed an examination of heart and lungs and the determination of blood pressure by auscultation. Abdominal examination was made by palpation and the testing of vision at ten feet. Then, following the passage of urine in the presence of the examiner, the employee was dismissed.

Women were examined also, but as the examination was necessarily less

complete, their records are not included in this report.

The age of the employees varied, as is true in all factories, and all nationalities are typically represented as they ordinarily apply for and receive work at all industrial establishments in a city. No re-examinations are included in this list, although many were made in the nature of checking up the physical condition of those whose defects required special placement.

As is well known to all industrial examiners, many of the defects exhibited are comparatively easy to remedy. The question comes up always, however, What shall be done with these employees? A year ago the spirit of cooperation in the rank and file of employees was unfavorably influenced either because of the independence of labor as a whole or of the usual "don't care" spirit of all human beings when things are going well. More recently it seems that at least the more intelligent of the workmen are willing to take suggestions

*Read before the Association of Industrial Medicine, and the section of Industrial Medicine and Public Health, College of Physicians, Philadelphia, Pa., February 11, 1921.

as to means of attaining better health and thus be better able to meet the competition for employment which apparently is becoming widespread.

Choice and Compulsion

But the general question is still open as to what means shall we employ to improve the health of the worker. Is it to be force, persuasion, or suggestion? With regard to force, medical ethics opposes saying to any man, "You must do thus and so to remain at work or to get a certain position," unless such a dictum is definitely a case of protection as appears under the discussion of hernia. At once the enmity of the workman is aroused by compulsion and, although he may, in the initial instance, do what he is forced to do, would he consult the physician at the plant in any subsequent emergency? And that is the crucial test of the industrial physician, for he must secure the confidence of the worker at the plant, making the men his friends, the same as in private practice. There is the tendency in industrial medical work entirely to overlook the side of the employee, and in the rôle of the patient, his needs are paramount.

Persuasion, too, is a wrong method; a doctor who has used up a half hour or so in convincing a man of his need to be operated on for enlarged and diseased tonsils, a hernia, or any other such condition, receives undue blame if anything goes wrong either during or after operation, such as hemorrhage in the tonsil operation or recurrence of the hernia. The whole story goes through a plant and loses the physician friends that he has previously made by hard, conscientious work.

The better method, as in private practice, is merely to tell the man the conditions found, enumerate the procedures that could be undertaken for relief, and then, in the light of the value he places upon his health and ability to work, let him select his own method of treatment. Should he decide to have operative correction, or whatever the doctor may consider the proper treatment, the doctor can then help the man in his selection of surgeon, or hospital, or appliance. Perhaps some will say this is passing up the responsibility, but the element of coercion enters into the man's mind when the physician paid by his employer says, "You should have this done."

There is an important psychological difference in these methods of procedure, and if the employee voluntarily chooses his own course when the va-

rious roads are pointed out to him, he has more self-respect and a better attitude toward his employer than if he were told to take the road to the right. Frequently when such things are explained to the workers, they desire to consult their family physicians, which, incidentally, it is our practice to advise all to do. Usually the family physician agrees with the doctor in the plant as to the contingencies and he takes the initiative as to what should be done. This advice, since the employee is paying for it, he does not resent.

To be sure, compulsion plays some part in such an ultimatum as this: "If you can see no better than that without glasses, your work will have to be changed," which in a skilled or semi-skilled worker means demotion to the plane of a common laborer, with accompanying decrease in income; but in such a case the man feels that he himself is deciding to have his eyes properly refracted, and he will shortly ask where to have the work done and will not take exception to such remarks, for ultimately he makes his own choice.

Another question arises: Is each employee to be apprised of any irremediable defect found and of which he doesn't know, such as a heart lesion, or high blood pressure, or tuberculosis? It was the rule in this series to tell every man his exact physical condition in addition to making accurate notes on it. This procedure is advisable, for how is the man to be made happy in a change of work unless he knows it is for his own benefit and is willing to cooperate?

Applied to Old Employees

Again, in a general way, how shall we treat applicants for work as compared to the employees already at work when found to be defective? Every applicant for work rejected for disabilities exhibited should be told the cause of rejection, and in case a remediable defect was the causal condition he should be told the same thing as the man already at work, namely, how this defect could be corrected, and, if corrected, it is well always to be able to assure a man that he could then secure employment, if any were to be had, thus again giving him the choice of his own procedure. If the defect is not subject to remedy the man is told just why he is a menace.

On the other hand, in the case of the older employees with irremediable defects, one is able to do a world of good by transfer to suitable work and by giving advice as to what to do to

keep the condition from progressively getting worse. Some men, naturally, are found too ill to work, as in the case of decompensated heart lesions and tuberculosis. These should be told of the danger to themselves and to those with whom they work, and should be put into competent hands for help. In case of some employees whose length of service, loyalty and position in life have been considered, they should be taken care of in some way, such as a pension, by the company. In fact, such action is fast becoming a general practice, even though the fact is not widely advertised. At any rate, no employer should throw out an old employee without some sort of physical or financial benefit. As this may sound like advocating compulsory health insurance as agitated by various labor unions, let me state here that I am absolutely opposed to it as a remedy for existing ills.

The idea in physical examinations in new employees, however else it may be stated, is that the employer can keep the unfit out of his plant, but at the same time, by holding up or postponing employment of those with badly decayed teeth, markedly defective vision, bronchitis, contagious diseases of all kinds, including skin and venereal diseases, hernia, severe varices without support, pleurisy, etc., until these conditions are corrected, he also actually forces health on applicants for work. Thus, by having only physically fit men and women in a plant, he greatly increases the productivity of the employees, thus increasing the income of workers as well as himself, and so all are benefited.

In the long run this can result in no harm, provided the labor market is sufficient, as it is at present. While the applicants are compelled to better themselves physically should they wish to work in a particular plant, still if it is clearly stated at the time of physical examination that such conditions exist, and until such time as they are corrected the applicant cannot go to work, certainly he will do what he can without feeling any animosity toward the firm for rejecting him, especially if he gets the same answer at several plant employment offices. The several major defects merit a brief discussion.

Defective Vision

In 21.4 per cent of the men examined the vision was 10/20 or less in one or both eyes. I have made an arbitrary ruling that no man with an uncorrected vision of less than

10/30 in a skilled worker and 10/40 in an unskilled worker should be given employment. In case of those already working in the plant the same rule applied, but in this case the man was told of his defect and that if he wanted to be able to compete with men able to see well in the same job he would have to have something done or else be transferred to some unskilled position paying less wages and but in which there was no danger connected. Again, even though the vision were 10/15, in the presence of symptoms of eye strain, or if errors in the man's work were attributable to defective vision, he was told of his needs and transferred to other work until such corrective measures were taken and then given his old job. If any of these defectives were discovered to be unable to pay an oculist's fee they were told of hospital clinics where such help could be had gratis, and all were warned against the optometrist.

Those blind in one eye or with one eye missing, making up 1 per cent of the total, were all rejected or gradually eliminated because of the possibility of the loss of sight in the remaining eye and subsequent total blindness.

Diseased Teeth and Gums

At least 31.3 per cent showed two badly decayed teeth with or without pyorrhea alveolaris. In case of applicants the employment of those with six to eight or more black snags of roots with pus exuding from the sockets was postponed until the offending members were removed. I felt that in the average case far more than half the battle was won if the teeth were removed, for the man would get false teeth very quickly when he found he was unable to chew his food. With those in the plant it was very difficult to convince the average man that a tooth which was not aching could possibly be a source of trouble, but once the word had gone around that I was insistent upon clean mouths the number appearing for examination with raw, sore gums from recently extracted black roots grew rapidly. With the others I used suggestion as to the foulness of their mouths by making various revolting comparisons, and I got results, as seen by subsequent check-up examinations, at which time I found the mouths clean and the men grateful.

Nose and Throat Conditions

Enlarged and diseased tonsils were found in 8 per cent of those examined, and only in those with a history

of repeated attacks of tonsillitis and quinsy or of some of the cardiac and arthritic complications was the removal of tonsils suggested. No rejections were made for this condition alone and only in case of an acute attack at the time of examination did we postpone the employment of any of the sufferers from diseased tonsils.

Deviated nasal septum was present in some degree in 16.3 per cent of the men. All were informed of the condition and told of the possible necessity of correction if repeated attacks of rhinitis occurred. It had no bearing whatever on employment.

Deafness was present in 0.7 per cent of cases. All were rejected in case of such applicants as could not, except with difficulty, hear the spoken voice. Those already in the plant were placed in safe positions if not already so favored, in order to preclude the possibility of these men not being able to hear danger signals.

Flat and phthisical chest, with abdominal breathing, occurred in 3 per cent of cases. If this existed without any other active disease in the chest both new and old employees were advised as to how it might be in part overcome by exercise, especially in the young. This particular type of man, however, was kept under observation and checked up from time to time regarding weight and general condition.

Cardiac Conditions

Myocarditis was found in 0.8 per cent of cases. In this number are included arrhythmias without any dilatation of the heart, but not involvements of the type usually spoken of as juvenile or respiratory types. Unless the worker already in the plant held a rather easy position, effort was made to have him transferred in case he was symptomless, especially if the condition were accompanied by high blood pressure, as it usually was. Those with symptoms were usually referred to their family doctor or some suitable man for treatment. They were usually laid off until all symptoms disappeared and were taken back only if their records were worthy. All applicants with this condition were rejected.

Endocarditis, which classification includes valvular disease as shown by murmurs and enlargement of the heart, represented 2.3 per cent of those examined. Those already at work, if compensated and without any history of decompensation, were let alone unless the work was particularly laborious, in which case lighter work of some type was furnished.

If decompensated, they were laid off until such time as they were again fit, following treatment. When they were considered ready to return to work they were given an appropriate position should their previous services warrant it; if not, they were not taken on again. Applicants with aortic or pulmonary valvular disease or mitral stenosis were all rejected. In case of mitral regurgitation the work to be done, as well as the general condition of the patient, was considered, and usually such were put to work in a suitable position. In the case of skilled workers already in the plant it was a difficult matter to transfer these men because of the lessened income which must necessarily ensue. The men and foremen were both told of the conditions and things were left as they were.

Incidence of Tuberculosis

Unquestioned tuberculosis represented 0.8 per cent of the series. These were all laid off, if at work, with advice as to where to go for help, either to a tuberculosis dispensary and eventually a sanitarium, or to the family doctor. All applicants with this condition, even if only suspected, were rejected. In case of suspects already in the plant, these were all given light outdoor work with hygienic and dietary advice, and frequently checked up as to weight and the physical findings in the chest, and if the disease progressed they also were laid off.

Surgical Conditions

Unilateral hernia represented 5.1 per cent and bilateral 1.8 per cent of the total examined. There was only one case of femoral hernia, the rest representing the inguinal type. These figures bear no relation as to whether the protrusion was complete or incomplete. The New Jersey law absolves the employer from responsibility in case of the indirect type of hernia, but does not, of course, relieve him in case of an injury to the contents of an already existing sac. Therefore it was deemed advisable to give the sufferer the choice of the radical cure or a properly fitted truss in case of the old employees. Every applicant with hernia was rejected unless the man was especially skilled and his work not particularly arduous, in which case he was permitted to go to work provided he wore a satisfactory truss.

Hydrocele affected 0.6 per cent of the series. If the condition was pronounced, proper treatment was advised; if small and symptomless, it

was not interfered with in case of those already in the plant. In applicants a hydrocele larger than a goose egg was a cause for rejection unless the man was especially fitted for some important duty and the men available for the position few. When larger than a man's fist, all hydrocele cases were rejected.

Varicocele occurred in 5.3 per cent, but none were rejected because of this condition and all were advised to wear a suspensory for comfort. All were advised of the operative procedure possible if they were not relieved by a suspensory.

Gonorrhea and syphilis in the infectious stage were found in 0.7 per cent in case of the former and 0.4 per cent in the latter disease. In case of men already working the men were laid off with the promise of their jobs again when they were cured or non-infectious. If not already under treatment, these men were advised where to receive proper care and were warned specifically against quacks. This course must be conceded as justifiable because otherwise employees will not consult the doctor in the plant concerning venereal diseases for fear of permanently losing their positions.

Naturally, in an effort to keep venereal disease out of a plant all applicants suffering from any of these diseases were rejected, but at the same time were told where proper treatment might be obtained.

Hemorrhoids were present in 8.5 per cent. All cases showing this condition were examined by rectum as well for possible carcinoma, but none were rejected for this condition alone. All were warned against constipation and were informed of the relief afforded by operation.

Flat feet presented in 3.6 per cent of the men and none is here included unless moderately severe or painful. These were advised to wear supports and, if not relieved, to take exercises aimed at the strengthening of the foot and calf muscles. Only those with difficulty in getting around and pain on standing were rejected.

Stiff joints presented in 0.6 per cent of cases. The men already working were usually in positions that they could take care of, but where such cases were badly placed, a transfer to such was effected. In the case of the new worker, unless the job fitted the individual's ability to care for it he was rejected. Here let me say a word of the need for the industrial physician to make a job analysis of his own, so as to be better able to help the employment manager to fit the

round peg into the round hole. I have found that an occasional trip through the factory is of great help in learning the name and nature of each job. Otherwise, unless this is always considered, one is working in the dark as to the needs of the job and the man.

High Blood Pressure

More than 150 systolic blood pressure characterizes this classification, which includes 7.8 per cent of the series. This figure is an arbitrary one taken for classification. The sufferer already working, if symptomless and uncomplicated by cardiac or renal disease, was not disturbed in his position. If, however, there was danger of attacks of vertigo or greatly increased pressure due to severe exertion, effort was made to have the man transferred to a safe place of labor, even though the work might be the same.

If complicated by albuminuria, as some were, or with improper cardiac action, I always had them see their family doctor for observation and treatment. Rejection was made of all above 170, if uncomplicated, and those above 150, if complicated, as this appeared the only safe way.

Chronic suppuration, whether from bone or soft parts such as an ischio-rectal abscess or suppurating adenitis, was a cause for rejection of applicants; if already at work, proper treatment was given. This type of case is relatively infrequent, but such conditions occurred often enough to demand a set policy.

In 3.3 per cent there was some form of skin lesion, not including eczema rubrum. Various types were met with, of course, but only those of contagious type, such as scabies and impetigo, were laid off until cured, if at work. Instructions were given in all cases as to proper treatment and the precautionary measures to be taken. The others were merely informed of the proper treatment, if they were not already receiving it. In applicants, eczema, if bothersome, and the work to be done were wet, and the easily transmissible types were rejected, but acne and psoriasis were passed unless they were so severe that the fellow workmen might object to the appearance of the patient. In the Campbell plant, especially, care was exerted to prevent the appearance of skin diseases in workers handling food. All permitted to go to work were advised to get treatment and were told of the usual long duration and of the persistent effort necessary to effect a cure.

Varicose veins were present in 4.7 per cent in moderately severe form or worse. Eczema rubrum was present in 8 per cent of the cases showing varices, and three severe varicose ulcers were encountered. Those of the men already at work were strongly advised to get elastic support, either a stocking or a bandage, and in case of men in particularly hazardous work, where the shin was apt to be struck and thus induce ulcer development, these men in the plant were told of the dangers of ulcers developing under the existing conditions. In such locations some men wore shin guards. Operation was discussed but not strongly urged. Applicants with proper support were permitted to go to work, but those severe cases with ulcers or eczema rubrum were all rejected.

Disease of the Kidneys

In 2.6 per cent of five hundred urinalyses albumin was present in the urine. No microscopical examination was made, but the urine of all those noted was clear. This condition was noted in two types of employees,—the undernourished and semi-sickly youth and the adult with some cardiac or arteriosclerotic changes. The cases were about equally divided. The work of each case was investigated and if not too heavy was not changed, but all were urged to see their family physician for treatment of the condition. The applicants showing albuminuria, whatever the cause, were rejected and advised to get in touch with a doctor for treatment.

Numerous other conditions were noted in occasional cases and each was taken care of as it arose, but all in the same manner as herein indicated, differently in the case of men already at work and in those about to be put to work, but the conditions herein stated are representative of all the defects.

A few specific instances of the transfers effected may not be amiss here. A weigher with less than 10/200 vision in one eye and 10/70 in the other was put to pushing trucks until he was fitted with glasses. A laborer on a wringing machine, with a blood pressure of 205, subject to giddy attacks, was put to cutting tanned skins in half. A boy on a buffing machine who developed a dry cough was transferred to a machine stretching wet hides. A deaf man working near machinery was changed to unloading freight cars. A man working in an overheated atmosphere was losing weight and grew tired easily. He was transferred to a ware-

house handling empty boxes. A man with painful flat feet was given a high stool and was able to continue with the same work he had done before while standing all day long. A man, rather intelligent for a laborer and with a long record of loyal service, was given a job as night watchman when, due to cardiorenal disease, he was no longer able to continue in previous work. A man with eczema was transferred from wet to dry work, etc.

In conclusion, in summing up the work done, several points are emphasized as of prime importance to the examiner:

(1) The necessity of the doctor knowing his plant so that he can fit the man to the job and the job to the man.

(2) The necessity of having the subject stripped so that all defects can be noted.

(3) The necessity of allowing sufficient time for each examination so that the proper advice can be given the men, for thus they realize that the doctor is telling them things for their own benefit as well as to increase production by getting them physically fit.

(4) Fearlessness on the part of the examiner in checking up the treatment being given by other doctors for various defects.

(5) Finally, the industrial physician ceases to be ethical he becomes absolutely subservient to his employers and forgets the humane side which he should show the employees in treating them as individuals.

Lives Lost in Mines

The United States Bureau of Mines, in summarizing the report from the various state mine inspectors, shows that 158 men were killed during May, 1921, in and about coal mines in the United States as compared with 163 last year during the same month. This is a decrease of five fatalities, or about 3 per cent. The average number of lives lost during May of each year from 1913 to 1920 has been 176. During the first five months of the present year 806 men have been killed by accident at coal mines as against 874 for the corresponding month in 1920, a decrease of sixty-eight fatalities, or 7.8 per cent. These figures represent a fatality of 4.01 per million tons mined in 1921, and 3.57 per million tons mined in 1920.

Labor Camp Sanitation of California*

Comfort and Normal Home Life With No Lapse in Health or Citizenship Standards is the Objective

By R. JUSTIN MILLER, ATTORNEY AND EXECUTIVE OFFICER OF THE COMMISSION OF IMMIGRATION AND HOUSING OF CALIFORNIA, SAN FRANCISCO, CALIF.

IN "Immigrant Health and the Community," recently issued as one of the series of "Americanization Studies," by the Carnegie Corporation, on page 367, is to be found the following statement concerning labor camp sanitation in California.

The Commission of Immigration and Housing of California has developed standards for labor camps which may serve in many respects as models for the country. The problem in California is peculiar because of the climate and the characteristics of the Mexicans, who are a predominant element in the agricultural sections of the state. The Mexican laborer generally has his family with him, and they move as a unit from one place to another. For these workers the commission has provided small family houses and supervision of sanitary regulations. It has been equally successful in its work in the mining and lumber regions where the labor camps problems are similar to those elsewhere in the United States.

This appreciative statement is correct so far as it goes. However, if the value of California's work is to be properly understood, and fully utilized by other agencies, the statement must be greatly enlarged. Though many of the labor conditions of California are undoubtedly peculiar to that state, at the same time, the very

diversity of labor conditions which do exist, makes it possible in a study of these conditions to visualize the labor camp conditions of practically the whole United States. It is true that the agricultural industry of the state constitutes one of its most important interests, but the elements of that industry range from the staple products of the extreme South, such as cotton, rice, and citrus fruits, to the staples of the extreme North, such as apples and grain. In California are to be found the highest

and the lowest elevations of land in the United States, and a wider range of temperature where humans are employed than any other state. The map shown in Figure 2 will indicate generally the areas in the state in which labor camps are located. The map is not complete in this respect, for during each year, some parts of the state cannot be reached by the comparatively small force of inspectors available.

What is more, the enumeration of mining and lumber camps in addition

Fig. 1—Suggested layout for a model camp, giving elevations, distances, and in general the required equipment needed in such a camp

*This report will be concluded with Part II. in the December issue of THE NATION'S HEALTH.

Fig. 3.—This camp layout is a fair example of what camp conditions should not be

to those of agriculture, does not by any means complete the list. This fact will quickly appear from an examination of Table I.

Total number of camps.....2,022
 T—Indicates temporary camps.
 T & P—Indicates temporary and permanent camps.
 P—Indicates permanent camps.

The titles "fruit camps," "grain camps," "construction camps," "mining camps," and others listed in Table I are subject to much greater sub-classification, covering as they do almost every branch of activity which can properly be classified under those heads.

In general the industries in which permanent camps are used are ones in which there is a long season of employment, extending throughout the year, or over a period of several months each year. In general the industries in which purely temporary camps are used are agricultural. These it must be remembered are industries of sufficient importance to warrant the calling in of extra labor during the harvest season. The many products which can be handled by the farmer and his family are not included.

The year-round nature of California's crops can well be shown by the following monthly crop analysis

Fig. 2.—This map indicates generally the areas in the state of California in which the labor camps are located.

of industries in which temporary camps are used (in addition to truck gardening which takes place throughout the year):

January.—Citrus fruits—including

oranges, lemons, limes and grape fruit—cotton, rice.

February.—Asparagus, citrus fruits.

March.—Asparagus, citrus fruits.

April.—Sugar beets—thinning, etc.—asparagus, citrus fruits.

May.—Berries, cherries, barley, wheat, asparagus, citrus fruits.

June.—Apricots, table grapes, berries, cherries, oats, barley, wheat, asparagus, sugar beets.

July.—Apples, apricots, peaches, figs, pears, berries, cherries, table-grapes, oats, barley, wheat.

August.—Sugar beets, cotton, hops, raisin-grapes, table-grapes, prunes, plums, apples, apricots, peaches, figs, pears, oats, barley, wheat.

September.—Walnuts, rice, wine-grapes, raisin-grapes, table-grapes, sugar-beets, cotton, hops, prunes, plums, apples, peaches, figs, pears.

October.—Olives, citrus-fruits, walnuts, rice, wine-grapes, raisin-grapes, table-grapes, sugar-beets, cotton, apples.

November.—Olives, citrus fruits, rice, sugar-beets, cotton.

December.—Olives, citrus fruits, rice, cotton.

Problem is Intricate

The intricacies of the labor camp problem in California, too, cannot be limited to the peculiar characteristics of the Mexican laborer. Although this is an important phase of the problem it is only a small part of it. The native born Americans, themselves, still constitute by far the most important part of the seasonal labor army. Anyone who has seen the exodus of the mothers and school children to the orchards and fields in vacation time can well understand that fact, as can one who knows of the great numbers who come by wagon and "flivers" from as far away as the Mississippi River, "seeing

Fig. 4 In arrangement and location the camp shown here is highly satisfactory. This is a feasible arrangement when the work and location are fairly permanent

Fig. 6—This tent platform with canvas cover is a type of the sleeping tent recommended. Dining tent and kitchen are of the same construction

America first" and incidentally paying as they go by working along the way. Last winter in Sacramento, at an impromptu mass meeting of unemployed (men) those who had called the meeting were surprised to find that approximately ninety-five per cent of those present were Americans; many of them ex-service men. Sacramento is one of the greatest labor distributing markets of the state and men of the more roving sort are to be found on the streets and around the employment agencies of that city at all times of the year.

It is true that the figures given regarding the mass meeting mentioned above do not constitute a correct index of the percentage of Americans who live in California's labor camps. Table II, entitled "Nationalities of Employees in California's Labor Camps" will indicate the nature and extent of this phase of the problem. The proportions vary from year to year; in some years the total of foreign-born predominating and *vice versa*. It will be noted that during 1920 there were more native born than foreign-born, while the figures for 1921 show a preponderance of foreign-born. It will be noted also that in 1921 the Japanese number nearly twice as many as the Mexicans, and that there are approximately as many Chinese camp employes as Mexicans. The figures for 1921 will be tremendously increased when the reports come in for the busy summer and autumn months.

TABLE II. NATIONALITIES OF EMPLOYEES IN CALIFORNIA LABOR CAMPS.
(During 1920 and the first six months of 1921)

	1920	1921

Total 57,767 16,983
Total number of camps where information on nationalities was not available 325
Population of these camps..... 15,691

The foregoing introductory statement will provide a background for an analysis of the specific problems involved in the work of labor camp sanitation together with the legal requirements relating thereto and the

inspection and educational methods which have grown up in connection therewith. The history of the work covers a period of only eight years, or since August, 1913. Prior to that time there can be only speculation as to the number, character, and quality of labor camps in California. It is certain that there were some good camps in the state at that time and some very poor ones. Very substantial protests had been made against some of the more deplorable conditions; a spirit of serious discontent had grown up among the workers; and the rapidly increasing menace to health, morals, and property had become very evident. The state legislature of 1913 took the first necessary steps to meet the situation, by the passage of the Camp Sanitation Act of that year. The Act took effect just seven days after the now famous Wheatland Hop Riots of 1913, in which two public officials and two workers were killed. The riot grew out of the bad camp conditions existing on the ranch where it occurred; these bad conditions being used as propaganda by some professional agitators who were working in that neighborhood.

The enforcement of the Act by the Commission of Immigration and Housing was begun during the following winter and has resulted in the practical elimination of conditions such as those which existed at that time.

Definition of Labor Camp

The Act as originally drafted was made to apply to all camps "where five or more persons are employed." This is the closest approach to a definition which is to be found and it remains the same to the present date. The question has been asked

Fig. 5—Purely temporary camps are made habitable by specified portable equipment. It is a real economy in the long run to provide good camps

many times: "Why stop at five?" Of course, as a matter of fact it is as much a labor camp if four or even three persons are employed as if five or ten happen to be there. The answer is that any number less than five approaches too closely to the one family situation of the ordinary farm, where the hired man or the two or three hired men are still regarded to some extent at least as members of the family. One of the most important effects of the representation of the "embattled farmers" in our legislatures has been to exempt the farm from the provisions of much beneficial legislation. The farmer complains bitterly of his inability to keep his own boys on the farm and of the trouble he experiences in getting and holding reliable farm labor, but if you suggest to him or to the farmer legislator that the provisions of the Workmen's Compensation Act or of the Camp Sanitation Act should be made applicable to the farm, he complains again, even more bitterly, and with his vote "protects" himself from such legislation. Eventually its beneficial effects will become so apparent that the scope of the law will be extended as a matter of course.

The Camp Layout

"Bunk houses, tents, or other suitable sleeping places" are required to be furnished for all employees. Of course many camp operators have supplied such facilities from time immemorial, but "in the old days" many operators furnished no facilities except those which nature had already provided. Piles of straw, creek bottoms, even manure piles, and the ground itself often constituted the only equipment available to the camp laborer.

Fig. 8 Along with improved sanitary conditions, an advantage in efficiency and stability is afforded by the provision of recreation rooms and features for entertainment

The bunk houses, tents, etc., are required to be kept in good structural condition "and so constructed as to provide shelter to the occupants against the elements and so as to exclude dampness in inclement weather." It is necessary, of course, that great care should be used in choosing the original camp site and in locating the camp buildings. Usually good clear land, well drained and conveniently located, can be easily found. Sometimes it is a serious problem to find a good camp site and then all that can be done is to make the best of conditions as they exist. It is surprising how frequently, when these camps are allowed to locate themselves, they are to be found in swampy depressions with involved drainage problems, when ideal grounds could have been secured only a few yards away. Figure 1 is a suggested layout for a model camp, giving elevations, distances, and in general the entire equipment needed in such a camp.

In connection with the plan shown in the figure the Commission issues the following set of rules:

Rules for Location of Camp

(1) Every camp should be located as near as possible to a plentiful supply of pure water.

(2) Every camp should be located on well-drained ground. Low plains, swamps and wet areas should be avoided, on account of both the discomfort attached to wet quarters and the possibility of affording breeding places for malaria-bearing mosquitoes.

(3) When a camp is built on the side of a hill a deep ditch should be dug above it to prevent the drainage water during the rain from running through the camp.

(4) As sunshine is the best disinfectant, camps should be located in open spaces. Exception to this rule should be made in the case of temporary fruit camps which operate during the hot and dry weather, where shaded locations should be chosen.

The photograph in Figure 3 showing a bad camp layout, is sufficient to speak for itself. In decided contrast to the insanitary condition shown in this camp are the well arranged camps shown in Figures 4 and 5. In many cases the problem of camp location is a complex one, because of the short "season" or because of frequent changes in location as in the case of highway construction camps. It may be found sometimes that although the "season" which requires the establishment of the camp is comparatively short, at the same time, it will be more economical to build a permanent or semi-permanent camp, or one which can be moved practically intact from place to place. Frequently, of course, the season is so short or the work is so isolated that a purely temporary camp must be used. Fortunately the expense of equipment in such cases

Fig. 7—Community camps are often possible in districts where work on small farms is accessible from the community camp which provides a home for the workers for the whole summer

is usually not so great but that even then the operator can see that it is real economy in the long run to provide good camps. Where this is true the operators are usually instructed to build tent platforms and side frames over which a tent can be set up, during the season; the canvas being stored during the balance of the year. Camps of this character are well illustrated by Figure 6. The photograph shows only the sleeping tents, but the dining tent and kitchen can be arranged in the same manner. Camps of this character are also frequently used by highway contractors and are moved from place to place or broken up at the end of each job.

A very interesting development

which is growing out of the comparatively large expense to small operators when individual camps are maintained is the establishment of "Community Camps." A good idea is given in Figure 7 of the results secured by one cooperative community effort of this kind. The camp shown in this photograph is located near a small town in the San Joaquin Valley in the center of a deciduous fruit and raisin-grape district. Good paved roads are very general throughout the district and it is possible for the workers to go easily from one farm to another, using the community camp as a home during the whole summer. In this way many small producers find a steady supply of labor without

the trouble or expense of maintaining their own camp. The number of these community camps, usually maintained by associations of growers, are increasing rapidly throughout the state and the equipment supplied is frequently more elaborate than required by the law. This tendency is a growing one also among many of the operators of permanent camps, such as the lumber and mining camps. The recreation room shown in Figure 8 is a good example of the comfort and means of diversion provided for laborers in these camps. In some camps large halls, equipped for dancing and motion picture exhibitions, are also to be found.

(To be continued)

The Warehousing of Dispensary Supplies

By RALPH W. ELLIOTT, M.D., MANAGER, MEDICAL DEPARTMENT, NATIONAL LAMP WORKS OF GENERAL ELECTRIC COMPANY, NELA PARK, CLEVELAND, O.

NO DOUBT various industrial organizations have adopted some plan or other for the solution of problems arising in the administration of widely separated subsidiary medical departments or dispensary service.

It has been found that there are undoubted advantages in the centralization of buying and in the distribution of all medical, surgical and dental supplies from one source. As a result of more than five years' experience we have perfected a system for the handling of this troublesome problem. This scheme enables the Medical Department to supervise the type of supplies used and to check up and standardize methods of treatment. The details will necessarily vary according to the individual needs of different organizations, but the essentials as outlined herein will serve as a working basis. In addition to the supervision mentioned above, there is an undoubted saving effected in the purchase of such supplies because of the advantage of buying in large quantities and further in the supervision of certain special formulae which have been found advantageous in the treatment of cases frequently met with in our dispensary service.

Purchase of Supplies

The active agent in the scheme of operation is the Purchasing Department which buys all supplies on the recommendation of the Medical Department. The Purchasing Department maintains a warehouse stock

upon which the various dispensaries in our widely separated Divisions draw by requisition. The Purchasing Department maintains a continuous inventory of all supplies on hand. A "Maximum" and "Minimum" amount has been fixed which is advisable to carry in stock. These maximum and minimum quantities depend, not only upon total volume used during the year by our dispensaries, but also on the quantity prices that we have been able to secure by placing orders to the best advantage.

In our experience the supplies that are ordered, which do not appear on this Warehouse List, are surprisingly small and are confined, as a rule, to certain articles that are of use only in a dispensary located where local conditions make it necessary to depart from the established practice.

In general, all orders that are placed for articles not included in the Warehouse List are referred by the Purchasing Department to the Medical Department for approval. This is to eliminate unnecessary extravagance and also to endeavor to confine our supplies to items listed in our warehouse stock. Not infrequently it has been found that other items ordered are so nearly identical with supplies in our warehouse that with a word of explanation standardized articles can be furnished from the warehouse which are perfectly satisfactory.

In the actual makeup of the warehouse list there are several points that we have learned by experience

which should be noted in order to avoid a certain amount of confusion. Various articles, for convenience, have been classified under different headings and have been printed on separate sheets in order to facilitate the making of carbon copies. These sheets are then attached to, and made a part of, the standard order form. The order number on this standard form appears on each separate sheet of the warehouse list.

All the supplies have been made up in standard packages the unit of which corresponds to the amounts best adapted for use in our several dispensaries and further corresponds roughly to the sizes of our shelf bottles and containers.

Under "Special Formulae" have been listed various remedies which, by experience, have been found especially valuable in the treatment of certain cases in our own industry. The ingredients in these special remedies do not appear on the Warehouse List but are furnished to each dispensary in detail in order that the doctor, dentist or nurse in charge may know exactly what they contain and so be governed in dispensing.

A stock as comprehensive as that indicated in the accompanying lists should only be supplied where there is a physician in charge of the dispensary. It is both unwise and perhaps illegal for a nurse to dispense from such an assortment except under the supervision of a physician.

All supplies received in the ware-

house are checked by a doctor or dentist before being placed in stock.

This should not, of course, be regarded as a complete list applicable to every type of industry, but must

be varied according to the peculiar needs of that industry, the proximity of hospital service to each dispensary, and with consideration of the age and sex of the majority of the workers.

The lists appended are revised about once or twice a year in accordance with suggestions by the plant physicians as to the usefulness of the remedies and supplies listed.

Ohio Rules on Hospital Contracts

THE Industrial Commission of Ohio, after conference with hospital representatives of the state, has completed a set of rules and regulations governing its contracts with hospitals for the care of workmen's compensation patients. While the new rules are not materially different from those which have been in force previously, they are more comprehensive and also more clearly defined, and are expected by the Commission to be the means of eliminating some grounds of dissatisfaction between the Commission and the hospitals in the past. A draft of the rules, which are retroactive to July 1, follows:

(1) (a) *A Hospital Patient*.—An individual appearing on the record as an admitted patient but will not include patients applying for after care following discharge from a hospital or from the care of a physician.

(b) *Unit Census Period*.—Twenty-four hours from midnight of one night to midnight of the next.

(c) *Patient Day*.—Appearance on the census of treatment rendered entirely within a unit census period.

(d) *Private Room*.—A room containing not more than one patient's bed.

(e) *Semi-Private Ward*.—A room containing more than one patient's bed, but not more than four beds.

(f) *Ward*.—A room containing more than four patient's beds.

(g) *Donated Service*.—Service of an individual rendering continuous service to a hospital for which no direct comparable monetary compensation is made.

(h) *Donated Supplies*.—Commodities such as are currently consumed in a hospital's operation.

(2) The basis of compensation of hospitals for the care and treatment of Industrial Commission cases shall be the average patient-day cost (per capita cost) of operating the contracting hospital during the previous calendar year, as determined by satisfactory data reported to the State

of Ohio, Department of Health, under Section 1236-6 G. C.

(3) The Industrial Commission will enter into formal contract with each hospital for each calendar year for the care of compensable cases at a rate equal to the patient-day cost of operating each hospital.

(4) The average patient-day cost shall be determined by dividing the total cost of operation by the total number of days hospital treatment given in the same period.

(5) The total number days hospital treatment for any given period shall be the sum of the number of days treatment given each day of the period. The number of days treatment given each day shall be the patient census as of midnight of that day plus the number of patients who have been both admitted and discharged during the unit census period. Each birth shall be recorded as an admission on the day of birth. Deaths shall be recorded as discharge on the day of death.

(6) The number of days treatment for which compensation may be claimed for a compensable case shall be equal to the number of times the patient appears upon the hospital census, provided that one day may be charged for patients both admitted and discharged within the twenty-four hour census period.

(7) The total operating cost shall include all money disbursements legitimately chargeable to operation, and may include such sums for donated service and supplies as may be deemed proper.

(8) Claim for addition to actual operating disbursements to make allowance for donated service will be recognized only when a detailed statement of service for which such claim is made is submitted in the annual report to the Department of Health.

(9) A schedule of fees to be allowed for donated services shall be fixed annually for the calendar year by a committee representing the organizations donating the services, the Department of Health and the Industrial Commission. The Chief Medical Examiner of the Industrial Commission representing the Commission as Chairman, shall appoint the committee members representing organizations donating service.

(10) The cost of all professional, scientific and ordinary services and supplies incident to the diagnosis, care and treatment of patients while in the hospital, except physicians and nurses' fees, shall be included in the operating cost, provided that such other service as may constitute a bona fide transaction between the patient and party other than the hospital shall not be included in the operating cost of the hospital. The evidence of such bona fide transaction shall be the non-appearance of any accounting for such services in the books of the hospital organization.

(11) Any claim for compensation for professional, scientific or ordinary service rendered an industrial commission patient which does not appear in the hospital accounts as bona fide transaction between the hospital and the patient, shall not appear in the hospital statement as a claim for compensation. Such claim shall be made in a separate statement by the party rendering the service. This shall not be construed to include individuals referred to a hospital solely for x-ray or laboratory service.

(12) A statement presented by any hospital to the Industrial Commission claiming compensation for services rendered shall specify:

(a) The total number of days treatment given.

(b) The number of days in private room, semi-private room, or in ward.

(c) If in semi-private room or ward, the number of beds in the ward.

(d) The total amount due for services rendered.

(e) The amount received from any other source for services rendered the same patient during the same period.

(f) The source of any payment received by the hospital in addition to that allowed by the Industrial Commission.

A statement shall be rendered for each case admitted. The character of service with respect to room or ward shall be that specified by the physician in charge of the case.

(13) The contract between each hospital and the Industrial Commission will definitely state which of the following services are included in the operating cost of the hospital: (a) Room and board; (b) Emergency; (c) Staff nursing; (d) Operating room; (e) Anesthesia; (f) X-ray; (g) Limited or complete laboratory.

No additional claim above the pa-

tient-day cost for services contracted for will be allowed. What limited laboratory service is specified, the scope of the service shall be specified.

(14) On petition from either party, disputed cases will be referred for decision to a committee appointed by the Chief Medical Examiner acting as chairman, said committee to represent in addition, the Ohio Hospital Association, non-members of the Ohio Hospital Association and the Department of Health. The committee will meet quarterly, and petitioners for hearing shall appear in person. Any petitioner not satisfied with the decision of the committee may appeal the case to the Industrial Commission.

(15) Whenever a hospital shall neglect to furnish data necessary for computing cost per patient per day, in accordance with these rules and regulations or shall neglect or refuse to enter into a contract on the above basis with the Industrial Commission of Ohio, compensation shall be made such hospital on a flat rate of not to exceed three dollars per day, no extra charges being accepted.

Recent Compensation Decisions

THE death of a city fireman, resulting from unusual exposure while fighting a stubborn fire on a bitterly cold day, is not due to accidental injury, so as to entitle his beneficiaries to compensation, even though there was expert evidence that the ice which froze on his neck and head had injured his spinal cord by pressing on the vertebrae.

Within the Workmen's Compensation Act, which provides compensation only for accidental injuries, the word "accident" is used in the popular and ordinary sense, as an unlooked for mishap or untoward event, which is not expected or designed, and compensation cannot be awarded for an injury received in the course of employment through natural causes where the employee was no more subject to the injury than others similarly employed.—*Savage v. City of Pontiac Sup. Ct., Mich., July 19, 1921, 183 N. W. 798.*

THE Saint Louis Court of Appeals has held, June 21, 1921, that where a building laborer of experience was directed to cut a hole in a brick wall for a girder, his employer's failure to furnish goggles for him was not a breach of the employer's duty. The danger of being

struck in the eye by a flying particle of mortar caused by the use of hammer and chisel was an ordinary risk incident to the work in which he was engaged, and the employer is not liable for his injury when the laborer did not request the employer to furnish goggles.—*Wulfert v. March Brothers Construction Company, 232 S. W. 243.*

THE Supreme Court of California, August 2, 1921, awarded compensation to a truck driver whose crushed body was found within the line of the trail, made by the wheels of his truck. The evidence was held sufficient to support the findings of the Industrial Accident Commission that he was crushed to death by being run over by the truck. The Court states further that the burden is on the applicant for compensation to show that the injury arose out of as well as in the course of the employment; there being no presumption that because an injury occurs in the course of employment it arises out of or because of such employment.

If the incapacity of the truck driver with heart disease to drive his truck was caused by a heart attack brought on by exertion, sudden

shock, or excitement incident to his employment on the highway, compensation may be recovered for his death by being run over after falling off. But where the proximate and immediate cause of an injury is from disability arising solely from an idiopathic or subjective condition, compensation cannot be recovered under the Workmen's Compensation Act, though the injury clearly occurs in the course of employment.

The mere fact that an employee's state of health is such as to expose him to greater risks in performing his duties, or at times to incapacitate him from danger incident thereto, does not render such damages and risks less incident to the employment than if he were better able to meet them.

Where two rational conclusions can fairly be drawn from the evidence, one sustaining and the other opposing the right to compensation, the conclusion adopted by the Commission is beyond the scope of review by the court. A rehearing was denied September 7 and the Court held that the Commission's direct finding of the ultimate fact that the injury to deceased truck driver, who was run over by his truck, occurred in the course of and arose out of the employment cannot be disturbed by a negative finding that "in some unexplained manner, which, however, was probably not connected with any heart or other subjective ailment, he was caused to be thrown or to fall."—*George L. Eastman Co. v. Industrial Accident Commission*, 20 Pac. 17.

THE Supreme Court of Michigan, July 19, 1921, held that the evidence that a compensation claimant who had been employed as a foreman and inspector, which was skilled work, and who was still unable to perform the duties of that employment because of injuries received, though he had been employed by the employer since the injury, was still disabled, since he could not perform the duties of his previous employment, sustaining the findings of the Industrial Board.

In the same case the uncontradicted medical testimony that an operation of a minor nature on a workman's arm offered a good chance for restoring the use of his hand, which otherwise would be permanently disabled, and that the operation was attended with little or no risk, and could not injure the arm, was held not to sustain the Commission's finding that the workman's re-

fusal to undergo the operation at his employer's expense was reasonable.

An injured employee owes to his employer and to society the duty to adopt reasonable means to terminate his disability so that the unreasonable refusal of an employee to submit to an operation for which his employer agreed to pay warrants the suspension of compensation payments for total disability until he does undergo the operation.—*Myers v. Wadsworth Manufacturing Company*, 183 N. W. 913.

THE Iowa Supreme Court, July 14, 1921, gives a more liberal interpretation of the requirements of the Factory Act. It was there held that an employer may be under duty to an employee to guard dangerous machinery although the facts of the case do not bring it within the so-called Factory Act (Code Supp. 1913, sec. 4999 or 2).

The facts of the case are recited in the opinion of the Court: "The plaintiff alleges that defendant owned and used a steam traction engine, with which, together with other machinery, he was engaged in various lines of work, including the shelling of corn for others desiring such service, and that in carrying on said business he employed the plaintiff to operate the engine and assist in and about the operation and management of said machinery; that while so employed, and in the line of his duty operating a corn sheller with the power afforded by said engine he attempted to reach a lever by which the gear shifting apparatus of the machine was controlled, and in said act the glove upon his hand came in contact with some unguarded cogwheels, with the result that his hand was so drawn into the meshes of the machinery and so badly crushed and wounded as to necessitate its amputation. Plaintiff further alleges in his petition that "defendant was negligent in that he failed to provide him with a safe place in which to work and that he failed to furnish safe machinery with which to work."—*Hainer v. Churchill*, 183 N. W. 624.

THE Supreme Court of Washington, July 28, 1921, affirmed the order of the Superior Court in awarding compensation for a disease, the proximate cause of death. The facts in the case are stated. On December 6, 1919, one Fred Anderson while engaged in an extrahazardous occupation received a cut in the foot from an ax. Immediately after

the accident he was taken to the bunkhouse located near the place of the accident where he received first aid. The wound bled somewhat profusely before the bleeding was finally checked, leaving him in a weakened and fainting condition. After the wound was dressed he was placed in bed; but, complaining of cold, he was taken to a stove in the bunkhouse where a hot fire was burning. The accident happened at about ten o'clock in the morning and later in the day, possibly about the middle of the afternoon, he desired to be taken to his home, some twelve miles distant. An automobile was called, which could not approach the camp nearer than about one mile, and this distance he was compelled to walk. The weather was cold and otherwise inclement at the time, and Mr. Anderson was exposed to it until he arrived at his home about seven o'clock in the evening. Shortly thereafter his wound was dressed. At this time he again complained of being cold and on the same evening had a chill. Two days later he developed lobar pneumonia. His illness immediately became severe, and he died from his effect December 28, 1919.

After the death of Mr. Anderson, his widow, made application to the Industrial Insurance Commission for compensation. The Commission rejected the application, basing its rejection upon the ground that the injury to the foot was not the proximate cause of Mr. Anderson's death. From the order of the Board there was an appeal to the Superior Court of Grays Harbor County, and that Court reversed the Commission's order, directing that her claim be allowed. From the judgment of the Superior Court the Commission appeals to this court. . . . "the fact that Mr. Anderson may have been imprudent in exposing himself to the weather in his condition does not militate against the right of his widow to compensation for his death. Nor is it necessary that the ax wound should have been of itself the cause of the death. It is sufficient if it was the proximate cause—the cause which directly set in motion the train of events which brought about the death.

"In our opinion the evidence justifies the conclusion and the judgment affirmed."—*Anderson v. Industrial Insurance Commission of Washington*, 199 Pac. 747.

Tuberculosis is defended by three allies—poverty, bad housing and drink.—Sir William Osler.

INSTITUTIONAL HEALTH

The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents

Detroit Provides Care of Tuberculous Children

Favors Physical Health, and Gives Full Expression to Childhood Emotion and Instincts

BY HENRY F. VAUGHAN, D.P.H., COMMISSIONER OF HEALTH, DETROIT, MICH.

IMRESSED by the success of the tent camp for malnourished children which was conducted during the summer of 1920, the Detroit Department of Health has now provided a permanent structure to house one hundred children. This will later be enlarged to accommodate twice this number. The camp site is the spacious grounds of the Municipal Tuberculosis Sanatorium near Northville, about twenty-five miles northwest of Detroit.

Penalties of City Life

There is something fascinating about the open country in the summer time. We think of unending stretches of brownish-green fields, of swimming pool, fresh vegetables, milk, and then, after sunset, that delightful tired feeling which hastens sleep amidst the lulling influence of the crickets and other things which are accustomed to chatter on a summer's night. It seems a simple combination, and yet the pity of it is that thousands of a city's children can do little more than dream about such an exist-

The roofs are steep pitched and are surmounted in many places by weather vanes, making a picturesque grouping of buildings admirably adapted to their purpose of relieving these air-starved children.

ence. For most of them summer means hot pavements, hot shadeless yards, heated houses, airless rooms, and—well, there is nothing particu-

larly stimulating about this outlook. Most youngsters get through with it, although the babies too often wilt and die off before the cool relief of autumn.

Hardest of all does the summer hit the little chaps who haven't an average physical makeup—the anemic, the undernourished, those with tuberculosis already manifesting itself, those living with tuberculous fathers, mothers, or brothers and sisters. It is to this group that the new summer camp opens its doors.

Two years ago the nurses of the Health Department of Detroit submitted the names of one thousand one hundred children who should be in open air schools throughout the year. There was room for but 150. Since then space has been provided for another hundred. There will be more accommodations when school opens in the fall, and with the increasing facilities planned it will not be long before there will be room for all.

The Board of Education is now planning to establish open-air rooms in all new buildings and in many of

The several units are identified with plaster reproduction of Mother Goose fables—Three Men in a Boat, Old King Cole, Humpty Dumpty, etc. The high gables, quaint doorways and other unusual features delight the childish imagination.

the existing buildings. This will save the long rides to the few schools given over altogether to open-air classes.

In the fight for better health more and more attention is being paid to the school child and the pre-school child in order to neutralize those evil precursors of tuberculosis—physical defects, undernourishment and bad hygiene.

From a height and weight survey in the public schools of Detroit last January, it was found that 6.7 per cent of pupils below the high school were 15 per cent or more underweight. The group of children who were 10 per cent or more underweight represented one-fifth of the school population.

Special attention must be given to this question of malnourishment in order to cut off the supply of tuberculosis victims at its source. This last year a carefully controlled nutrition experiment has been carried on with one hundred children, fifty being furnished a hot noon lunch at the school and the other fifty used as a control with no supplementary feeding. Home visitations by nurses and dietitians have been paid to both groups in order to stimulate active home cooperation. It has been brought out that the most potent retarding influences to growth are physical defects, secondly, the lack of home cooperation and thirdly, the lack of a balanced diet or sufficient food. It will be the policy of the Health De-

Make conditions right for the children to live a free and healthful life and adult health conditions will largely take care of themselves. Physical deterioration, especially in tuberculosis conditions, may usually be charged to unfavorable factors in the early environment.

partment in the coming year to enroll in nutrition classes only those who are free from impairing defects, or in other words, those who are "free to gain."

In the meantime we must deal with the heritage of the past, namely, those children who have not been rescued from the initial unfavorable conditions and who in consequence are now precariously balanced between health and tuberculosis.

There is now being completed a Municipal Tuberculosis Sanatorium located on a nine hundred-acre tract near the village of Northville. This will open this autumn and will have a capacity of three hundred beds for

adults. The Sanatorium has entailed an expense of two million dollars.

In addition to this unit there will also be erected a preventorium for children, with accommodations for two hundred, this structure costing a quarter of a million dollars.

The third institution to be established on these grounds is the permanent summer camp for children, which was ready for occupancy about the middle of July.

The Summer Camp

The new structure consists of two elongated one-story buildings with solid concrete floors and side walls of stucco on metal lath. The roofs are steep pitched and are surmounted in many places by weather vanes, the face of the entry ways being decorated with Mother Goose figures, such as the "Cow Jumping Over the Moon," and "Wise Old Owl," the "Old Lady Riding on a Broomstick," etc.

In the rear of the main building is located the spacious diningroom, and back of that the kitchen. Two detached buildings house the lavatories and toilets.

A complete water supply and sewerage system was installed. In addition to the shower baths there is a swimming pool with concrete bottom in a nearby stream.

Altogether there are about six thousand four hundred square feet of dormitory space, which allows over sixty square feet per person for one hundred children. Some of this space will be occupied by those in charge of the camp. The second story over the diningroom is also available for this purpose. Storage space, as well as offices and locker space, is provided.

The staff includes nurses, recreation workers, camp quartermaster

The regime requires the proper balance of exercise and rest, and the rooms permit the freest circulation of air

This year the Camp introduced more than one hundred children—undernourished and tuberculosis exposures—to the joys of outdoor life under conditions favorable to body and mind.

and assistants, cooks and helpers. A physician for the care of the children was in attendance on certain days.

Selection of children to be sent to the camp is carefully conducted on the basis of surveys and medical records.

As the open-air schools remain open all summer, it was possible to recruit a new group for the summer camp among those who were unable to attend the open-air schools for want of space.

The homes of Detroiters whose children were sent to the camp were beehives of excitement during the month of preparation. Clothes were to be got ready and marked with tape. There was necessary a physical examination. The delicious days of anticipation of a wonderful life in the open passed usually too slowly, and beyond that there was the enticing probability of again being restored to the health balance which means usefulness and efficiency in the adult days ahead. There is much satisfaction in the feeling that a community can by the expenditure of money bring health and happiness to some of its temporarily less fortunate future citizens.

What a Hospital Library Service May Accomplish

By CARL H. MILAM, SECRETARY, AMERICAN LIBRARY ASSOCIATION, CHICAGO, ILLINOIS

THE other day," wrote a hospital librarian during the war, "I managed to get admitted to a ward which had been closed to me for almost a week because of the influenza epidemic. When I appeared in the doorway, the men in the nearer end of the ward gave a joint sigh of relief that came like music to my ears. Almost in a perfect chorus they exclaimed, 'Yes, here she comes! Here comes the book lady!' Farther down the ward, one lad, who was very young, greeted me with real tears in his eyes. 'I have been lying here for days wishing you would come,' he said."

Hundreds of experiences like this during the last few years have convinced librarians who have had the good fortune to serve in hospital libraries that the book finds an important and comparatively new field of service in the hospital.

Therapeutic Value

When the war awakened public consciousness to the loneliness and suffering of the men in the hospitals, the American Library Association's librarians in the camps began the specialized work of supplying reading matter to the patients. From that beginning there was developed a reasonably complete hospital library service in the Army, Navy, and Marine Corps establishments. Later this

hospital library service—with the other library service for the military organizations—was taken over and is now being maintained by the United States Government.

Following the Armistice the wounded men were returned to America by the thousands, and the American Library Association organized an extensive library service for the disabled men in the Public Health Service and so-called contract hospitals. The num-

ber of books in use in these hospitals was recently estimated at around fifty-five thousand. In one hospital more than 2,500 books were read in one month and the total number of books read by Public Health Service hospital patients in March was nearly twenty-two thousand.

As the result of this specialized library service in hospitals for the soldiers, sailors, and marines, and for the disabled veterans of the war,

Administration by a trained librarian is one of the most important features of hospital library service. In addition to thorough professional training the librarian must possess infinite patience, sympathy, and tact, in order to encourage reading and direct it along the most beneficial lines.

"The library is the only thing that kept me from going crazy," said one man as he was being discharged from the hospital. Thousands of American ex-service men have felt the same way about the library service provided by the American people through the American Library Association.

Some one to talk to, something to read, something to think about—that is what the hospital librarian gives to each patient in the hospital. The convalescents who are able to leave their wards may go to the hospital library, but the little tea-wagon trucks take books to those who are confined.

there has come the new realization of the importance of libraries in the lives of men and women who are temporarily or permanently confined to hospitals. Many physicians and nurses who have seen the librarians at work have testified to the high therapeutic value of the service rendered by them and their books. Convalescents especially are eager readers. Many a patient has been aroused to take a new

volumes and a few ragged magazines in every hospital—is indicated by the following paragraph quoted from Miss Miriam Carey, one of the hospital library supervisors under the American Library Association, and now in charge of institutional library work in the State of Minnesota:

What the librarian of a base hospital library aspires to do is to get everybody to reading. In order to know how to do this, a leisurely sur-

in the ward with a book or scrap-book or magazine in his hand.

Library commissions in some of the states, public libraries in several cities and, more important than all, hospital authorities themselves, are taking a new interest in the development of this trained expert book service for the men and women in hospitals. The time may soon come when the library and librarian will be con-

The Salt Lake City Public Library is one of several such institutions which have established library service for hospitals. The convalescents are always especially glad to see the book truck coming.

interest in life because of the book he has read. Books not only help to kill time but they furnish something new to think about and something new to talk about. Many ambitious young men in the hospitals have turned the dreary hours of convalescence into hours of profit by the study of books on vocational subjects.

The specialized character of the service rendered by the hospital library of the new type—for there have always been a few scattered

vey from bed to bed is taken. After the soldiers get acquainted with the librarian and adopt her as one of their own folks, they do not hesitate to tell her what they want to read—far from it. And after one of these bedside visits she can tell them what they want to read if they are backward about it. To satisfy the wants of the sick soldiers it is necessary not only to take the book to the man, but to get acquainted with him. After this has been done the librarian and her orderly have the supremest satisfaction that can come to such workers, namely, that of seeing every man

considered as important parts of the hospital equipment and personnel as the laboratory and the head nurse.

Another feature of library service may logically be expected to grow out of this experience, viz.: the establishment and maintenance—probably by public libraries in cooperation with social service agencies—of a specialized library service for the sick, the wounded and the convalescent outside of the hospital. Although reading matter is plentiful and books

Since the need of hospital library work was demonstrated in Army and Navy hospitals, several cities and several states have sponsored such work in their civilian institutions. In Iowa, Minnesota and Nebraska systematic institutional work is under way, and all have appointed supervisors of state hospital libraries.

The daily visit of the librarian with her "book wagon" is an important element in the lives of the wards. Practically the only patients who refuse the opportunity to select some reading matter are those who exercise the privilege of ordering a book not seen on the wagon. Each man gets what he most enjoys.

are fairly cheap, still it is true that many thousands of those who are confined to their beds or to their rooms are entirely unprovided with the kind

of reading matter which they ought to have, and are quite beyond the reach of the helpful, stimulating suggestions about reading which will

make the book do its part in speeding up their recovery. New interests acquired through reading are an undoubted spur to recuperative effort.

Physical Education Plants for Public Schools*

Oakland, California, Arranges Adequate Schemes for Developmental and Corrective Exercise

By C. W. DICKEY, SUPERVISING ARCHITECT, OAKLAND PUBLIC SCHOOLS, OAKLAND, CALIF.

PHYSICAL education has loomed large in the planning of the new public schools of Oakland, Calif., under the recent five million dollar bond issue, partly because the school authorities believe it quite as important to provide for physical development as for mental, but also because a state law passed about four years ago makes it mandatory upon all school districts to provide physical training for all children from the kindergarten to the twelfth grade who are physically fit to receive it.

Fortunately, our climate permits exercise in the open air throughout the year except on a few rainy days. Thus the exercise floor or gymnasium proper is not as essential as in more severe climates, and can be eliminated where economy demands. The bathing and dressing facilities and administrative offices are, however, considered essential.

Individual Needs Cared for

Every pupil in the school is provided with an individual steel cubicle

Combination Gymnasium-Auditorium for the Elmhurst Junior High School. The stage is used as the girls' gymnasium, and the front of the auditorium for the boys' section. This plan forms the central motive of a large school building.

locker for his gymnasium suit. On the boys' side there are sufficient full length lockers to accommodate the street clothing of one class, varying

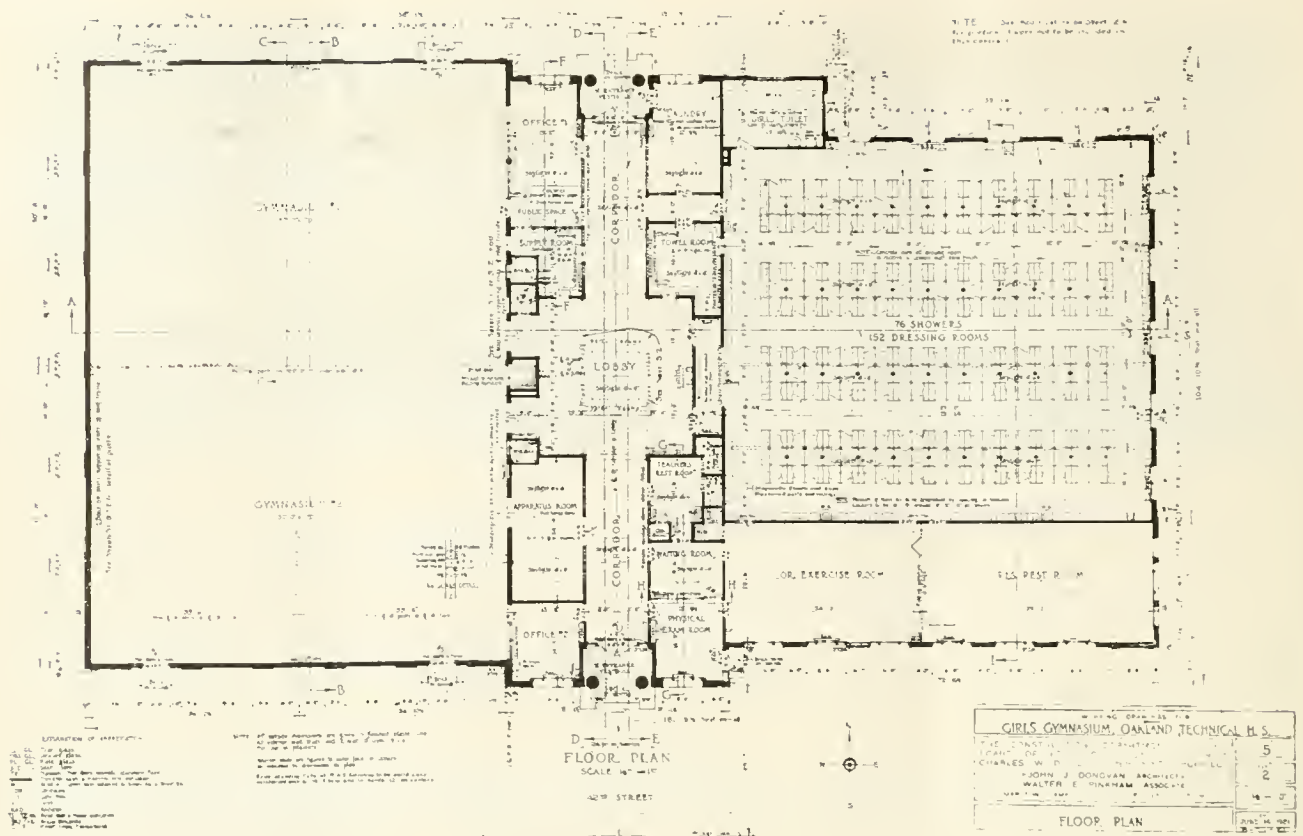

from sixty to one hundred and twenty-five in the different schools. These are used successively by each class, the bathing being in a general shower room. On the girls' side, small individual dressing booths are provided instead of long lockers. Each booth connects directly with a shower, two booths to each shower. The construction of these booths is of white enameled woodwork supported free of the floor on nickel plated legs.

The gymnasiums are generally individual buildings of wood, frame finished, with cement stucco on exterior walls, and with tile roofs. They are set between the boys' and girls' athletic fields.

The floor plan is arranged for the maximum ease of access and egress so classes will not interfere with each other, and provision is made on both boys' and girls' side for instructors' offices with shower and toilet, examination and first-aid room, supply and towel rooms, apparatus room, corrective exercise and therapeutic room. A rest room is provided for girls, with cots, tables, and chairs. Adjoining the dressing room is a toilet and, on the girls' side, a set of hair driers.

The plans of three typical gymna-

*The plans used in connection with this article are sponsored by C. W. Dickey, supervising architect, and Washington Miller, Louis Stone, J. J. Donovan, and W. E. Pinkham, associate architects.

The girls' gymnasium of the Technical High School is designed to serve a school of 2,500 pupils. The other half when completed will be for boys and will be similar to this plan with the exception of dressing rooms and showers.

siums are shown herewith. The girls' gymnasium at the Technical High School is for a school of 2,500 pupils, and constitutes the first half of the physical education plant. The other half when completed will be for boys and similar to the girls' quarters except as to dressing rooms and showers.

The gymnasium for the Alexander Hamilton Junior High School is much less elaborate and much smaller. It provides for both boys and girls for a school of 1,200.

The combination gymnasium-auditorium for the Elmhurst Junior High School shows a still more economical scheme. The building is so planned that the stage is used as a girls' gymnasium, and the front portion of the auditorium for a boys' gymnasium. The seats back of same being raised on tiers with a balcony above. The bathing facilities and other accessories are arranged along each side of the auditorium and stage. This plant forms the central motive of a large school building. The general school locker rooms and toilets will be noted near the main corridor. In thus providing a dual use for the auditorium a great economy in construction is achieved. The seats for the gymnasium floor are stored on special

trucks under the stage. The gymnasium accessory rooms are used as stage dressing rooms.

In all cases, the gymnasiums are arranged for social uses such as dances, the offices being then used as dressing rooms. The exercise floors

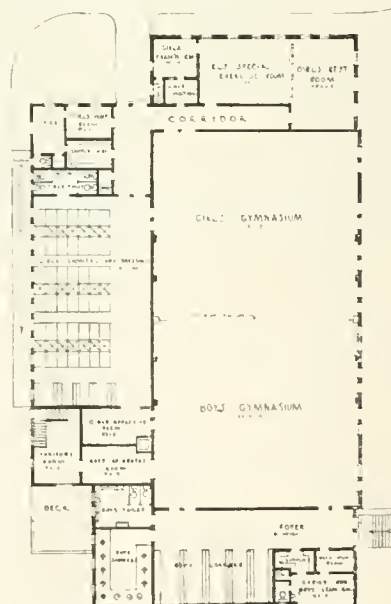

are separated by heavy patent folding door partitions so the whole space can be thrown open for these occasions.

Argentine Installs Physical Education

Regulations for the physical education of school children which have just been approved by the National Council of Education, the central educational authority of Argentine, provide for special classes in physical education, for the installation of conveniently accessible playgrounds, and for the appointment of teachers for each playground. The council also ordered the appointment of a commission to draft plans for the construction of school baths.

Oregon Survey of Feeble-Minded

A recent state-wide survey in Oregon shows that more than 75,000 men, women, and children, of a total population of 783,000, are dependents, delinquents, or feeble-minded. More than 500 school children of a total enrolled school population of 32,500 are more or less mentally deficient, according to a recent statement by the United States Health Service.

The Gymnasium of the Alexander Hamilton Junior High School, smaller and much less elaborate than the building at the Technical High, but affords ample provision for both boys and girls in a school of 1,200 pupils.

Care for Convalescent Cardiac Children

By MRS. BENEDICT ERSTEIN, PRESIDENT, MARY ZINN HOME FOR CONVALESCENT CHILDREN, WHITE PLAINS, N. Y.

ONE of the finest examples of enlightened private philanthropy is afforded by the Mary Zinn Home for Convalescent Children. Anxious to establish a memorial of some sort to their mother, Messrs. Martin and Arthur Zinn consulted the best equipped experts of the city before finally deciding upon the form that this memorial was to take. After considering many types of work, they finally decided to enter the field of caring for children convalescent from cardiac disease.

In the fall of 1919, an experimental home was established at Sheepshead Bay. The number of children cared for was limited and the most careful study was made of the requirements that a properly equipped building called for, the nature of service that must be afforded in order to assure the best results, the type of patient to be admitted, and the extent and nature of the after-care work that must be provided in order to assure a continuance of the good results achieved, through the treatment under supervision.

Planned After Try-Out

After the brief experimental period, a large estate was purchased on Namarck Road, White Plains, N. H. The main building on the property was completely remodeled so as to provide extensive porches, enclosed

rest room and sun parlor, dining room, kitchen, play room, wards, isolation room for patients confined to their beds, nurses' quarters, bath rooms, shower rooms, store rooms,

building with two class rooms. Another building was remodeled to form an isolation building, arranged in two sections so that each may be completely cut off from the other in case

Boyce

These little patients do not feel themselves greatly hampered and certainly are not unhappy under conditions that are properly adapted to their needs

etc. The ventilation throughout is perfect. Every possible safe-guard has been taken to assure comfort, sanitary conditions, and safety.

What had been the barn was completely converted into an ideal school

of necessity, each being provided with separate modes of ingress and egress, etc.

The Home accommodates forty-two children, and, although it has been in operation for less than a year and a half the demand on its facilities far outstrips the possibilities of accommodation.

Every thought has been directed to freeing the Home from any institutional aspect. The play room is a delight to the eye with its dominant blue and yellow coloring, its cheerful draperies, and its tastefully decorated bookshelves. The dining room is equipped with small tables. The reception hall was left untouched so as to retain the effect of a residence, and in many other details every effort has been made to preserve a homelike aspect.

Three Main Groups

The type of case upon which the stress is being placed is that technically known as the "sub-acute cardiac." With a breadth of vision not always evident in similar organization, there have been formed three directive groups of an unusual type. The Board of Directors is composed

Boyce

Alterations necessary to convert a residence into this institution for the care of convalescent children sacrificed none of the charms of a home atmosphere. The reception hall was left untouched.

Boyce
What had been a barn was converted into an ideal school building containing two rooms. With these children a physical handicap does not necessarily mean retarded mental development.

almost entirely of representatives of the various social service groups connected with the hospitals of the city. The president of this Board of Directors is Mrs. Benedict Erstein, and the vice-president, Mrs. Arthur Zinn.

Men and women, for the most part distinguished by their connection with philanthropic institutions of various types, were organized into an Advisory Board, the Chairman of which is Herman Block.

A medical board, the chairman of which is Dr. Charles Gilmore Kerley, its personnel including some of the leading pediatricists and specialists in cardiac diseases, gives constant care to the admission of children and proper medical treatment, and the conditions to warrant discharge of the patient.

The home itself is under the direction of a registered trained nurse, with registered trained nurses and assistants in charge of the children. A local physician is also a member of the staff, and visits the home frequently, giving personal attention to their physical care. All the members of the Medical Board are available for consultation and for treatment of children who have been discharged from the home. A trained nurse visits the homes of the children after they leave White Plains, and directs the home treatment to assure complete recovery.

Demonstrates Right Method

The predominant feature of the Home is, first and foremost, the happy spirit that is everywhere prevailing. The children do not look like patients. Their eyes are bright and clear, their

cheeks are blooming and round, and the halls are continually ringing with happy laughter. The meals are carefully regulated by a trained dietitian. The education of the children is under the direction of the Department of Education of the City of New York, which has assigned two teachers to the work, and which provides also for one of the teachers to remain in charge of afternoon recreation. The attending and admitting physician is at the home more or less frequently, at least once a week, in addition to which there are the occasional visits of the other members of the Medical Board and the constant visiting of the local practitioner.

The social value of this work is immeasurable. That it fills a gap in the general plan of social medical activity, cannot be questioned. What may be of even more importance than the restoration to health of the children who are cared for at the home, is the possibility that this home may demonstrate the proper method of convalescent care for children afflicted with cardiac disease. The interest which the project has aroused in the community speaks well for its fulfillment of a real need. The spirit of the donors is reflected everywhere; a spirit not of self-glorification, but of a whole-hearted desire to serve children.

Directors for Food Research Institute

The Carnegie Corporation of New York has announced that the election of directors of the Food Research Institute, which began work at Stanford University on July 1, under an agreement between the university and Carnegie Corporation, had been completed. In addition to Dr. C. L. Alsberg, who has been chief of the Bureau of Chemistry, United States Department of Agriculture, the board will comprise Dr. Alonzo E. Taylor and Professor Joseph S. Davis, now Assistant Professor of Economics at Harvard.

The National University of Mexico is organizing school lunches for poor children. University teachers and employees will voluntarily contribute a small percentage of their salaries for this purpose.

Boyce
All plumbing has been remodeled according to the most up-to-date sanitary standards. This view gives a good idea of one of the model lavatories

Control of Infectious Diseases in Hotels

By D. L. RICHARDSON, M.D., SUPERINTENDENT, PROVIDENCE CITY HOSPITAL, PROVIDENCE, R. I.

THE number of people who patronize hotels every year cannot be estimated with any degree of accuracy, but it is certainly very large. As a factor in the spread of contagious disease they certainly must be of considerable importance, although of course there is difficulty in tracing infection to this source because the populace is so transient. Whether a disease is contracted in any particular hotel is very difficult to determine, for the person may have visited several during the incubation period.

That vermin, particularly bedbugs, are a source of much discomfort, if not danger, anyone can testify who has patronized the cheaper hostelries particularly. The modern up-to-date hotels take great pains to attain cleanliness of their premises because it pays, and in them one is almost as safe as in one's home. There are a few criticisms which should be offered as applying to the best of them, and worst ones need severe censure.

Health Protection Necessary

The suggestions made apply equally to restaurants, boarding houses and apartment houses. Managers of such places of temporary abode owe it to themselves and the public at large to safeguard the patrons that are within their doors. The time has come when they cannot afford to neglect such an important matter. It is not necessary that construction and equipment be elaborate and expensive, for any well built wooden hotel, if under good management, can furnish as good sanitation and protection to its guests as the largest and most elaborate hostelries.

The possible sources of infectious diseases in such establishments are the employees—particularly those who handle food and drink—the water, milk, ice, and ice-cream, canned goods, and other foods which are sometimes infected, and by contact through such common utensils as the lavatory, soap, common comb and hair brushes, and contact with guests who are sick with infectious disease while resident there.

The more common diseases which may be contracted are typhoid fever, food poisoning, including infectious diseases caused by certain intestinal germs, respiratory infections, scarlet fever, diphtheria, etc.

It is highly important that every

More thought is given by the traveling public to convenience and to luxurious background in hostelries than to their potentialities for harm unless some fortuitous circumstance drives home a sense of the ever present menace of contagion. From the wisdom of experience, however, hotel men are learning that only eternal vigilance assures safety and are requiring that their installations in kitchen, laundry, refrigerating rooms and bathrooms shall embody the best principles of sanitation. The physical examination of employees and routine sanitary practices take care of the rest. Neglect in such matters should not be tolerated anywhere by the traveling public.

hotel have a doctor employed part time, or full time, depending on its size. The hotel manager should call him to see all sick employees, or at least ascertain what disease takes them from their work, and the doctor should always be consulted before an employee who has been sick goes back to work. If the manager believes that a patron is sick with some infectious disease, the hotel physician should be instructed to find this out by personal examination, or from the patron's own physician. A hotel is no place for acutely sick persons, nor should persons suffering from tuberculosis or venereal diseases be allowed more than transient accommodation. The supervision of the health of the employees is of very great importance. Many cities now require that all persons who handle food and drink be licensed after a proper physical examination. This is a very good practice, but the value of an examination once or twice a year is limited because employees are often sick between times. The periodic examination rules out largely persons suffering from tuberculosis, venereal diseases, some chronic skin conditions, and also typhoid carriers. It is highly important, then, that every employee taken acutely ill be seen promptly by the house physician. It is a wise provision to take every acutely ill employee away from work, especially if he is a waiter or kitchen

employee. Surely every person with intestinal symptoms suggesting typhoid, or persons with sore throats suggesting scarlet fever, diphtheria, and the like should be excluded until well, or non-infectious. The potential danger of a typhoid carrier or mild typhoid case in the kitchen or dining room is never to be forgotten. The employer should insist on a health certificate of every employee handling food and drink and insist that the hotel doctor see at least once every acutely sick employee. If the employee has gone to another doctor, the hotel physician can secure the diagnosis from him.

Every patron sick with an acute infectious disease should be removed to a hospital at once. The hotel manager cannot afford to disregard this principle, because if it proves to be a case of smallpox, or other highly infectious disease and, either if publicity be given it or an outbreak is actually started, the hotel's reputation will suffer severely.

In towns and cities where there are no hospitals it may be necessary that the sick person be treated in the hotel. The hotel physician should certainly have the supervision of every such case, with or without the help of another physician. He should be responsible for the prevention of other hotel guests becoming infected. The sick person should be strictly confined to his room and visitors restricted as much as possible. The technic to be employed should be that employed in the ordinary home.

Effective Isolation

There should be some card on the person's door to indicate to other guests to keep out of the room.

No one except the doctor, nurse or attendant, and nearest relatives should be allowed to enter the room.

The patient should be in a room connecting with a private bath, or at least there should be a lavatory. In the bathroom should be provided a scrub brush for the hands, preferably liquid soap, paper towels or small individual hand towels, with a receptacle into which to throw them after use. If an antiseptic solution is to be used, a basin should be provided in which can be made a solution of sulpho naphthol, a teaspoonful to the quart. The hands should always first be scrubbed with soap and water for

not less than three minutes before the use of the antiseptic solution and the immersion of the hands in the antiseptic solution should not be for less than one minute.

The doorknob on the side of the door facing the corridor should never be handled by those attending the patient until their hands are scrubbed.

The doctor nurse or other attendants and visitors as well should, while in the room, wear a washable outer garment, which garment should be left in the patient's room or bathroom when such persons leave the room, after scrubbing their hands.

The relatives and visitors must not be allowed to kiss the patient.

The eating utensils which necessarily must come from the hotel kitchen should receive careful attention, otherwise many of the guests might be infected by a single mistake. As few dishes as possible should be exchanged between the patient's room and the kitchen by leaving in the room all which do not need to be washed at every meal, or by the use of paper utensils which can be put in the waste and later burned. In the kitchen there should be a kettle or pan of water on the stove sufficiently large to accommodate all the dishes which will be returned from the patient's room. In large hotels which have steamers, one of these can be used for sterilizing the dishes. The person designated to get the dishes from the patient's room must not go in the room, but is to receive them on a tray and with them proceed to the kitchen without opening doors, asking someone else to open any closed door. These dishes, tray and all, should be put into the pan or steamer directly, the person's hands should be scrubbed at once. The dishes should be boiled or steamed for at least ten minutes.

The food should be delivered to the patient on the tray by the porter and he should not enter the room, but hand the tray to the attendant at the door.

Soiled linen can be allowed to collect in the room or bathroom, either being put in a bag or tied up in a sheet and put out of the way. Soiled baby napkins or other grossly soiled linen can first be washed out in the toilet bowl. When it is to be sent to be washed it should be put in a clean bag or sheet and carefully tied up. After delivery to the hotel or private laundry, it should be put in water about boiling point for at least twenty minutes. This can easily be done in a laundry washer by using water near the boiling point while the

washing process is going on. The water used for this purpose in commercial laundries is usually much less than boiling. This process will render the patient's linen harmless.

All waste should be collected in a large paper bag and taken to the furnace room where it should be burned.

Disinfection of Premises

After recovery or after a patient has been removed to the hospital, the room should be treated as follows: The dishes, linen and waste should be treated as has already been indicated. All the utensils and toilet articles possible should be boiled for at least ten minutes. Those articles which would be injured by boiling like money, nice brushes, shoes and other leather goods, etc., should be washed with soap and be allowed to dry in the sun if possible. The room itself is a slight source of infection. The mattress and pillows should be sterilized by steam or exposed to the sun and air for at least six hours. The bed, bureau, table telephone instrument, and other furniture should be washed with soap and water. Upholstered furniture, draperies, etc., can be aired in the sun. If the room has a hardwood or other washable floor, it should be washed with soap and water, as well as the floor and fixtures in the bath room. The woodwork about the door, including knobs and other wood finish, may be treated in the same way. After the room has been opened up to the air for at least twenty-four to forty-eight hours it is safe for occupancy. If antiseptic solution is to be used for cleaning purposes sulpho-naphthol, a teaspoonful to the quart, is cheap and does no damage.

There are certain features of the general management and equipment of a hotel that have a distinct bearing upon the transmission of diseases.

No hotel should allow the presence of vermin. Lice are known to be carriers of diseases. Bedbugs, although not known to be carriers of disease, are very troublesome and annoying. The dormitories should be well supervised and guests should be encouraged to report at once any vermin found. Bedbugs do not have the same favorable hiding places in the modern hotel as in the cheaper wooden structures, but they may be found even in the one ever so well built. The dormitory maids should be told to watch constantly for vermin and report to their superiors.

Roaches should receive attention. Food attracts them and it should not

be left about. Their breeding places may be sought out and treated successfully by many of the commercial powders and sprays. Two good formulas are as follows:

Liquid Bug Spray

Cresol 1½ pints
Oil cedar leaf..... 1½ pints
Naphthalene 1 pound
Kerosene to make 5 gallons.

Dissolve cresol, oil and naphthalene in kerosene and add enough kerosene to make 5 gallons.

A Powder

Sodium fluorid 10 pounds
Borax 5 pounds
Pyrethrum powder 5 pounds
Flour 25 pounds

The premises should be kept free from rats by the use of cats, poisoning, trapping, or by ratproof construction, and not having uncovered garbage about.

It would be highly desirable if each lavatory be so constructed that the water could be turned on by some other method than by soiled hands, such as a forearm or foot lever, and the washing of the face and hands be done in warm water which comes from a spray or spout to which is piped both hot and cold water, the mixture to be governed by the valves on each hot and cold water supply. Perhaps such a practice will come about in time. Certainly after washing no one should be allowed to wipe on a towel which has been previously used. Individual cloth towels should be provided, or else paper towels should be supplied.

Soap should be liquid soap, dispensed in individual cakes or in liquid soap containers, many of which are on the market.

No common drinking glasses should be allowed. Either drinking fountains or paper cups should be supplied. The common hair brush and comb should not be encouraged.

Dish Washing Methods

It is not probable that soiled dishes from the dining rooms are a very fertile source of disease, yet they probably are a factor. In the small hotels these dishes after being swilled should be washed in hot water and scalded before wiping. The wash water should be changed frequently. A very efficient method of sterilizing dishes in a larger establishment is the use of the mechanical dish washer, many types of which are on the market. The essential point being that the boiling water be used in the process.

No common towels should be tolerated in a kitchen. Each cook

should have his own towel, preferably hitched to the uniform in some way. Besides individual towels, only individual cloth or paper towels should be used.

Cooks should never taste and put the spoon back into the food again. In every respect the kitchen should be scrupulously clean.

The selection of the raw food is of importance in certain respects.

The raw milk supply should be vouched for by the Board of Health, but the manager should watch closely the bacterial count for this is an ex-

cellent indicator of the cleanliness in the preparation of and also of the age of the milk.

The water supply of public hostilities in small places where there is no safe public supply is of much importance. The drinking water should come from artesian wells or from a surface well which is so situated that there is no liability of infection from human excreta. The approval of the water supply should be obtained from the state or local Board of Health.

Oysters and other shellfish should be purchased from reliable sources.

Canned goods and olives may be the source of infection. No swelled cans should ever be used and, if there are many in a single order, all should be condemned. Ripe olives have recently been the source of serious outbreaks, but the United States Government has taken steps to see that in their preparation at the factory the germs are killed.

It is a good business proposition for any hotel, restaurant, or rooming house to see that such measures be instituted and carried out for the protection of their patrons.

The Infant Welfare Society of Chicago

Child Welfare Is a Study in Applied Economics.
It Is Both Humanitarianism and Common Sense.

BY LUCIUS TETER, PRESIDENT, THE INFANT WELFARE SOCIETY OF CHICAGO, CHICAGO, ILLINOIS

THE Infant Welfare Society as a corporation came into existence in 1911 as the outgrowth of the Chicago Milk Commission which, with other groups, had been laboring with the problem of getting a better milk on the market, encouraging institutions caring for children to use a better grade of milk, and providing babies in the poorer districts with a clean, pure modified milk during the hot summer months.

Endorsement of dairies making an honest effort to produce better milk, and legislation against careless producers brought about an improvement in the milk supply. Demands made on institutions induced them to buy better milk.

A central milk depot was established where milk was brought, pasteurized, modified and then sent to a few outlying distributing points. Here mothers came and were supplied with the required number of bottles of the required milk content for their babies. Mothers knowing not the rudiments of proper care of ordinary foods had no background for so keeping the milk that it was fit for the child's consumption a few hours after delivery during the extreme heat of the summer months.

However there is no gainsaying the advantage there was to some infants who were thus supplied and it was equally obvious that the problem was not a problem of the summer months alone but was a tremendous situation which needed constant thought throughout the year. An effort was successfully put forth to raise funds

making it possible to consider a twelve month program.

The Scope Extended

In the development of a twelve month program the accepted standards of an infant welfare program were striven for and success was early manifest. A corps of doctors and nurses was developed for consultation at stations and the consequent follow-up work in the homes. As an initial program but one such conference was held each week. Because the organization had done its first work as a milk distributing agency this phase of the work was not

easily disassociated from the wider program of prevention through education. For a number of years much milk relief was given, but the present policy is that milk, or any material relief, is given only over such a period of time as is necessary to get a relief giving agency in on the case. This policy has made it perfectly clear to the mother that the Society offers her nothing but a well baby as an inducement for placing the child under supervision. Endless streams of mothers might be persuaded to bring a baby to conference religiously were they to receive a never ending supply of milk for their effort, entirely los-

Expert knowledge on such questions as feeding and the prevention of minor ailments is passed on to the mothers. The work is permanent and valuable only in the degree that the mothers are reached on the educational side.

ing sight of the educational value which would make it possible for her to care for her own. Cases have been cited where the milk was shared with other members of families in which the mother had not learned the value of it as the next best food for her baby.

In the early years of the work the question was again raised as to whether or not it was being made too easy for mothers to discontinue breast feeding and to put the baby on an artificial food. This danger was entirely wiped out with the inauguration of weekly conferences with the mother. The technic of breast feeding was emphasized and the teachings reiterated again and again. An early effort was made to discourage the mother from expecting an issue of milk tickets as a reward of merit for having brought her baby to the conference. That the Organization was entirely justified in taking such a stand was clearly brought out in a survey recently made when there was much discussion concerning the price of milk and the battle of the increase in cost being fought by the babies rather than other members of the family. Despite the increased cost of the milk, it was found that mothers who had consistently supplied the smallest member of the family with his milk ration continued to do so. This was among mothers who had learned the value of milk as a food for the child through contact with the Infant Welfare Society and not among mothers who had had no contact of the sort.

The Infant Welfare Nurses carry instruction in milk modification into the home. The doctor indicates the formula and the nurse carries out his instruction in the home.

Side by side with the untrained mother, the trained worker notes the child's progress, weighs it and interprets the signs. Methods are adapted to the means at hand. The problem of the child extends itself to the problems of the parent as concerned with the child.

The aim of the Society is, to reduce the infant death rate and to improve the health of the coming generation—before birth, by caring for the mother and after its birth by teaching the mother how to feed and care for the infant.

Because the Society relies on the contributions of interested friends and socially minded citizens, who believe that not until we have made health education available to every living soul will we have a physically sound community, a very definite piece of work was undertaken as a demonstration. Such a demonstration has proved the value of the undertaking and such standards have been set up as have made forever impossible work less well done.

In 1911 with ten stations and ten nurses the death rate was 4.3 per cent as against a rate of 1.5 per cent in 1920 among the babies registered in the twenty-four Infant Welfare stations.

The name "District" is given to the territory not more than a mile square, covered by any one working unit of the Society. In these areas where the infant death rate has been highest districts have been organized. Definite boundaries have been established to prevent any overlapping of effort, to make all the work readily accessible to the mother, and to make it possible for the nurse to cover the territory in her home visits.

The "Station" is the centrally located meeting place to which mothers may bring their babies twice a week. The stations are located in the field houses of ten public parks, two nurseries, two social settlement houses, two dispensaries, and eleven are in buildings which it has been

necessary to rent because of the lack of other facilities. The plan has been to use whatever facilities were available and known to the mothers in the district. In this manner very close cooperation is possible between all agencies dealing with the problems of the district.

The term "Conference" is given to the semi-weekly meeting of the mothers who come to the station for the advice of the doctor.

The Work Is Educative

The work is done through specialized service. Mothers bring their babies to an Infant Welfare conference and there any mother living within the stated boundaries of the district is accepted. Only such history is taken as makes it possible for the nurse to locate the family the next day. The child is undressed, weighed—by volunteer workers when available—and then seen by the doctor. The doctor gives the baby a very thorough physical examination and advises the mother regarding the care of her child. Emphasis is placed first and always on the value of breast feeding. When a modification is necessary the doctor indicates the formula and the nurse carries out his instruction in the home. Stations are not dispensaries in any sense of the word as advice only is given. On this score and with such a program only the Society has had the cooperation of the medical fraternity.

Being cognizant of the tremendous existing need of preventive work with all children, it was after much deliberation that the age limit of two years was set. The generally known facts concerning the death rate over this early period coupled with the

*The two best reasons for

the two cans of pine-
apple, add enough
water to make two
quarts and add to the
dissolved Jell-O. When
cool and still liquid,
whip according to di-
rections on package.
Stir the pineapple into
the whipped Jell-O when
it is thick enough only
to drop—not run—from
the spoon. Set away
to harden. Serves from
90 to 100 persons at a
cost of three cents per
serving.

So many relishes and desserts are lacking in proper food value and so many foods of high nutritive qualities are untempting to the eye and palate, that it is apparent that any food which combines tempting appearance, delightful taste and a tendency to renew bodily tissue must be of exceptional value to the industrial worker.

Jell-O is far more than a "pretty" dessert. It possesses very valuable properties that aid in the upbuilding of the system, and is especially beneficial to those who are emaciated or exhausted. It exercises a marked influence on the economy of metabolism.

The ease with which so many delicious salads and desserts may be prepared with the use of Jell-O is one other factor that recommends this wholesome preparation to the industrial cafeteria manager.

A Jell-O treat will add to the satisfaction of the lunch period and help renew employees for the coming hours of labor. Workers want it. It's good for them.

Six pure fruit flavors: Strawberry, Raspberry, Lemon, Orange, Cherry, Chocolate. The new special package for institutional and restaurant use contains enough Jell-O to make four quarts of jelly.

Gallon Package

THE GENESEE PURE FOOD COMPANY

LeRoy, N. Y., and Bridgeburg, Ont.

The babies who are born must have a fair chance to survive and, having survived, must be given such health supervision as will make it possible for them to develop into adults sound in health, sound intellectually, and sound morally.

equally well known limitations of the finances of the organization made the program acceptable despite the fact that economically it was very bad to keep a child well until he was two years of age and then do nothing with him until he came up for school inspection. Such limitations as to age rendered it possible to make a very clean cut demonstration, and the re-

sults brought the confidence of citizens generally so that when an extended program was undertaken funds were made available.

Develops Obstetric Service

Despite every effort made only those babies were reached who had survived the terrific hazards of the first month of life. A program which

carried education and care to the woman in the early months of pregnancy was the only solution to the problem. In developing this obstetric service the Society has had the co-operation of Rush and Northwestern Medical colleges through whom only has the work been possible. Weekly prenatal clinics are held in five stations, and follow up home work is done by nurses of the Infant Welfare staff.

With the stimulus given by Children's Year to the complete story of child health it was possible to develop a long planned program with the child from two to six years. For years beautiful specimens of babyhood were graduated from Infant Welfare stations at the age of two years and took their unobserved, unsupervised place in the ranks of the uncared for runabout.

In twelve stations nutrition clinics have been established and there with the help of a staff of dietitians the two-year-old is carried and his mother guided and helped in making food provision for her family.

Thus thousands of Chicago and suburban citizens are making it possible for some eleven thousand other families to share the blessings of health education.

Scouting and the Nation's Health

Physical and Moral Fiber is a Sine Qua Non of Boy Scout Training

BY G. SHERMAN RIPLEY, SCOUT EXECUTIVE, HARTFORD, CONN.

UNCLE SAM began to sit up and take notice when the army medical examiners rejected for active service 35 per cent of drafted men. What was the matter with the health of the average American? If he was ineligible to serve as a soldier, how desirable was he as a citizen?

Attention was directed to the physical training which the boys of the nation were receiving. The search-

light was played pretty thoroughly on the public schools, and their program for developing the youngsters was frankly discussed. It was found that a surprisingly large number of school children received no physical education, while in many cases the training was perfunctory and superficial. Too often it was unaccompanied by instruction in hygiene and physiology.

It is not really the fault of the schools that the average youngster nowadays knows more about the parts and functions of a Ford than he does about the organs of his own body. The trouble is, there seems to have been no nation-wide and definite program of physical education. Steps are being taken to define and carry out such a national program in the near future.

But no matter how well such a plan

may be organized, the public school system will need help. The school only has a boy a few hours of the day, and all school training must be along compulsory lines. Here is where an important ally of the schools begins to function. This ally is the Boy Scouts of America, chartered by Congress, and headed by Warren G. Harding as Honorary President.

There is nothing compulsory about

"Dan Beard," one of the daddies of Scouting.

Blind Boy Scouts at Hartford, Conn.

Sherman's Polyvalent Vaccines

A more adequate and rapid immunity can be established with polyvalent vaccines than from an infection itself. SHERMAN'S POLYVALENT VACCINES rapidly stimulate the metabolism and defense of the body with a resultant prompt recovery in general acute infections.

Given early, bacterial vaccines almost invariably cut short the common pyogenic infections of the skin, mucosa joints and tissues;

Administered in advanced cases, they usually ameliorate or abbreviate the course of the disease;

Even when used as a last desperate expedient, they often reverse unfavorable prognosis.

The immunizing powers of stock vaccines are demonstrated by the prophylactic efficiency of typhoid vaccine. Bacterins made from selected, vigorous organisms are far higher immuno-producers than autovaccines prepared from feeble, degenerated organisms sometimes found in the patient's own specimens. Especially in acute cases, the PROMPT injection of a stock bacterin is decidedly preferable to the DELAYED injection of an autogenous one. The place for autovaccines is in chronic infections which fail to clear up under stock bacterins due to the prob-

able presence of some unusual bacterium.

Advanced inflammatory processes due to only one class of bacteria are rare, mixed infections being the rule. Therefore, COMBINED VACCINES, containing all strains likely to be present, give the best assurances of success; an unneeded variety of the bacterin is harmless and in no way weakens therapeutic response.

Thus the favorite invaders of the nose and throat are the pneumococcus, the streptococcus, the staphylococcus and the micrococcus catarrhalis, calling for Sherman's No. 40, and in chronic cases—when there is a foul odor produced by the Friedlander bacillus—Sherman's No. 36. In visceral infections, due chiefly to the colon bacillus with the pus cocci, Sherman's No. 35 is appropriate. In Neisser infections, if these organisms are not already allied with the gonococcus, the imminence of their entrance is so great that the rational combination is Sherman's No. 49.

When, particularly in grave cases, valuable time may be lost in securing the variety of vaccine especially recommended, it is always advisable to use the vaccine at hand which contains the predominant organism of the disease to be combatted.

Sherman's 10 Mil Container

This package has many superior features which assure asepsis, prevent leakage and facilitate the removal of contents. It is constructed on the well known Sherman principle.

The vial is amply strong which prevents breakage so frequent with shell vials.

We are exclusive and pioneer producers of Bacterial Vaccines. Originators of the aseptic bulk package. Pioneer in elucidation, experimentation and clinical demonstration.

Twenty Preparations.

Beyond the experimental stage.

"DAILY USERS OF VACCINES USE SHERMAN'S"

Clean-up inspection. A Boy Scout reporting on conditions found in a dirty yard. The report goes to the health and fire departments.

the physical education of Scouting. Although the training is wholly voluntary, this movement is one of the most helpful agencies for training America's boyhood into better health. On May 26, 1921 there were 407,824 registered Scouts in the United States. These were organized into 17,524 troops under the guidance of 120,000 men, all volunteers.

During its first decade Scouting has given more than 1,500,000 boys a training in ethics, hygiene and the value of camping in the open.

Scouting recognizes the fact that physical education is a great deal more than merely taking setting-up exercises. Hundreds of scout games and scout requirements which the boys pass in taking tests are aimed at genuine health education. Among the subjects of this nature, which take boys into the out-of-doors are: agriculture, athletics, bird study, botany, camping, conservation, cycling, first aid, forestry, gardening, hiking, horsemanship, life saving, personal health, physical development, pioneering, public health, seamanship, surveying and swimming.

Do the boys take these tests? Are they thorough enough to be of real value? To date the khaki-clad youngsters have taken some of the more valuable tests at the following rates: Athletics, 6,693; camping, 8,378; cycling, 7,623; first aid, 4,937; life saving, 8,781; personal health, 21,404; physical development, 3,660; pioneering, 5,251; public health, 20,691; swimming, 18,773.

There are more than sixty of these merit badges. When a boy wins

twenty-one of them (certain special ones included), he is an Eagle Scout, and may throw out his chest. The American Eagle has more than 2,500 of these Eagle Scouts under its wings.

In contrast with putting the arms up and charging forward with the left and right foot alternately (a good exercise—I use it myself), will the friendly reader put himself in the place of the Scout who is expected to pass the following:

Public Health

To obtain a merit badge for Public Health, a scout must:

(1) State the chief causes and modes of transmission of each of the following diseases: tuberculosis, typhoid, malaria.

(2) Draw a diagram showing how the house-fly carries disease.

(3) Tell what should be done to a house which has been occupied by a person who has had a contagious disease.

(4) Describe the method used in his community in disposing of garbage.

(5) Tell how a city should protect its milk, meat, and exposed foods. State what are the laws in his community covering this subject, and to what extent they are being enforced.

(6) Tell how to plan the sanitary care of a camp.

(7) State the reason why school children should undergo a medical examination.

(8) Tell how he may cooperate with health authorities in preventing disease.

(9) Produce satisfactory evidence

that he has rendered service in some effort recommended by the public health authorities in the interest of public health.

Physical Development

To obtain a merit badge for Physical Development, a scout must:

(1) Produce satisfactory evidence of habitual good posture.

(2) Have no remediable physical defects uncorrected.

(3) Produce satisfactory evidence of daily practice of hygienic habits and a thorough knowledge of a standard book on hygiene.

(4) Pass three of the tests, according to his weight, in the Athletic Schedule.

(5) Demonstrate proper form in running, high jump, hurdle, and shot-put.

(6) Make up a daily drill of ten exercises for scouts, giving proper exercise for whole body; present evidence of having practised this daily for six months and having taught the same to two or more boys for a period of three months.

(7) Demonstrate reasonable efficiency in two outdoor games requiring physical development; give evidence of having taught at least ten scout games to a group of boys, and know ten more.

To obtain a merit badge for Life Saving, a scout must:

(1) Go down from the surface of the water at least seven feet deep and bring up an object twelve inches or more in diameter, weighing not less than ten pounds.

(2) Swim twenty yards carrying a person of his own weight: (a) By a two-hand carry, using feet only for propulsion; (b) By a one-arm carry, using side stroke.

(3) Dressed in trousers, coat, and shoes swim fifty yards, then undress before touching shore.

(4) In deep water, demonstrate three approved methods of releasing death grip.

(5) Demonstrate Schaefer (prone pressure) method of resuscitation.

There is nothing like this in the average school curriculum. Observe that there is as much "do" as "know" in these tests.

But what is more important, the scout code of ethics is a positive factor in character formation.

Every scout must promise:

"On my honor I will do my best—

(1) To do my duty to God and my country, and to obey the scout law;

(2) To help other people at all times;

Not Only Her Poor Feet

The inefficiency of high heels and narrow, pinched toes is greater than most women believe. Ill-balanced shoes do more than discomfort the feet; they cause fallen arches, backaches, nervous strain, displacement of the internal organs, weariness, depression.

"Working women are the worst offenders," says Dr. Evangeline W. Young, of Boston. "It is the girls who are on their feet most who persist in wearing the highest heels. Sensible women have learned that they can increase their efficiency and even earn bigger salaries by wearing shoes built for solid comfort and health."

Without sacrifice of good looks, the Cantilever Shoe for women gives perfect comfort and perfect carriage. The last conforms to

the mould of the foot, with room for the toes, and with trim fit and support about the instep and heel. The outline of the sole and the set of the heel are designed to preserve the balance and the beauty of a NATURAL walk.

The flexible shank yields with every movement of the muscles. Instead of being bound to a rigid sole which retards the circulation and makes the foot weak, in Cantilevers the foot has liberty to exercise and bend freely and gracefully. This freedom of movement strengthens the muscles and prevents and corrects flat foot. By changing to proper shoes almost any woman can do more efficient work, avoid fatigue and accidents, and find greater happiness.

Cantilever Shoe

for Men & Women

What's a mere signal tower to a bunch of husky scouts?

(3) To keep myself physically strong, mentally awake and morally straight."

A Scout Is Clean

He keeps clean in body and thought, stands for clean speech, clean sport, clean habits, and travels with a clean crowd.

This extract from the Scout Oath and the Scout Law gives a boy a solid moral foundation upon which to stand. The venereal disease clinics

will have less work when all the boys in America have built these principles into their lives, starting at the impressionable age of twelve, when boys need the guidance of a moral rudder set true.

The author once heard Dr. Frank Crane say, "We are getting to be a nation of indoor people. We never go out of doors—except to go from one house to another!" Here, again, is where Scouting comes to the aid of the schools. School physical work

is largely an indoor game. Scouting is an outdoors game. Every first class Scout must swim fifty yards and take a fourteen mile hike. During 1920 160,000 boys went camping under Scout auspices. This year the number was larger. These thousands of boys are learning to use God's out-of-doors.

Scouting is breeding a generation of men who think of recreation in terms of the blue sky, and not the movies.

Short Tenure of Women's Jobs

THE Bureau of Women in Industry of the New York State Department of Labor has been attempting to find out to what extent this statement so commonly made by employers is true. Eighty of the largest firms in New York State were questioned. These establishments employed 14,597 men and 14,435 women. Included in the list are manufacturers of chemicals, rubber, shoes, textiles, soap, optical instruments, paper boxes, cut glass and candy.

While the turnover among women is higher than among men, the difference is not great. The significant fact is that where turnover is high among men, it is also high among women and where it is low among men, it is also low among women, which in the final analysis, is a gauge of the extent of maladjustment within each individual shop.

In a pamphlet issued by the Federal Board for Vocational Education (Bulletin No. 46), it is stated that the reason why labor turnover is higher among women than among men is be-

cause men, to a much greater extent than women, have persons dependent upon them for support and do not quit so readily. In analyzing the turnover of the 12 firms, however, these facts stand out with significance.

(a) That where turnover for a given shop is high, it has meant in three instances that the reason for the high rate of turnover among women was due to the high labor turnover in one department.

(b) That in the majority of cases, the women employees were doing the least skilled work. All turnover studies that have been made, show that turnover among the unskilled is higher than among the skilled, whether man or woman.

(c) The women employees on the whole represented a very much younger group than the men employees and turnover is usually higher among young workers than among the more mature ones.

(d) The records indicate in six instances a higher turnover rate among unmarried than among married women, and in six instances, a higher rate among married than unmarried.

The evidence obtained from the plants who have established employment departments in charge of trained executives showed a noticeable turnover decrease within a twelve months period. Women respond and react to a well organized, centralized employment department perhaps more than men, in that many of their work problems are personal problems and can be easily adjusted by a sympathetic and understanding employment director.

One manufacturer testified to the fact that he had reduced his turnover 50% by (1) comprehensive analysis of the requirements of each job; (2) careful selection of applicants; (3) comprehensive training of new hands; (4) systematization of promotions; (5) investigations of causes for leaving; (6) regulation of employment.

Gym games are used a lot by the Boy Scouts.

Attitude of the Physician to the Health Center

**Impartial Judgment and Common Sense Must
Discern and Retain the Changes that Spell Progress**

BY ALEXANDER LAMBERT, M.D., NEW YORK CITY

THE question as to what should be the attitude of the medical profession towards health centers is equivalent to saying: In what manner and how far is the medical profession willing to change its present method of practising its profession? Health centers represent but one means to be used for the socialization of the profession and the reorganization of the basis on which the service rendered by physicians shall be offered to the sick. What, then, are the conditions in the profession itself which require change from the present method so long used in the practice of medicine, that is, the individualistic care of the sick by the individual physician? If any change be necessary, is health centers the only scheme offered or is it the best one offered?

Looking Backward

One has only to look back for a generation to appreciate the great changes that have come about in the method of medical practice. Thirty years ago medical practice had just begun to become differentiated into the numerous specialties, and even the broad lines between surgery and medicine were just beginning to be defined. This specialization eradicated the idea that the general practitioner alone could solve all questions in medicine, and specialization in medicine has increased the medical value of the service rendered to the

Increased scientific knowledge in causation and prevention of disease has outrun scientific development of therapeutics, temporarily injuring medical service.

The test of ultimate values, however, lies in the efficacy of present working hypotheses. Applied art and theory are reciprocal and must be correlated to serve as a mutual check.

Science is the search for and development of truth which ceaselessly expands. Progress is change. Neither esoteric aloofness nor inflexible resistance to change will serve to stay the change that means progress.

people. It has benefited the profession economically and the public scientifically, because it has permitted men to develop an unusual skill in medical service along the lines of their particular interests without being overburdened with other portions of medical service which they considered distasteful. The resulting advances in surgical technic and the extension of therapeutic possibilities through surgical procedure have been so striking that they have caught the imagination of the public to the exclusion almost of the advances of other fields of medicine; and being of a peculiarly concrete nature, and thus

readily grasped and appreciated as definite concrete service rendered, highly specialized surgical service has been able to command enormous fees which heretofore had not been thought of in medicine. However advantageous this development may have been economically, it has not been without many drawbacks in its results upon the surgeons themselves and the rest of the profession.

Another great development of medicine has been the scientific study of the causation and control of disease, especially of the group of diseases that we designate as communicable. During this same period we have seen preventive medicine represented formerly by health departments with police power used only to prevent the spread of epidemic diseases develop into highly organized departments of the government controlling, not only the spread, but extending care in communicable diseases. The prevention of disease through sanitation, has been made effective through study in the scientific laboratories, through the manufacture and disbursement of vaccines and antitoxins and by therapeutic care in many diseases. One of the chief sources of pride to the medical profession in past years has been its development of preventive medicine and the domination and practically the eradication of certain diseases which a generation ago were of common occurrence and whose routine care formed a great part of the

medical service rendered to the community. All forms of laboratory service have been so enhanced in diagnostic value that clinical laboratory service is now a necessity for the intelligent practice of medicine. All these developments of medicine have so increased its scientific accuracy that it is of enormously greater value in the protection against disease.

On the clinical side the greatest achievement has been in diagnostic accuracy. The leaders in the profession have been those physicians who have made the great scientific discoveries in the laboratories and in the study of the science of medicine, or else in the specific application of the results of such study have shown in the diagnosis of disease that increased acumen which more clearly recognizes the different morbid processes. The great clinicians of the recent past have been men noted for their diagnostic abilities. Some of these leaders taught accuracy of diagnosis, but vigorous contempt of earlier therapeutic methods. Their students have gained in scientific accuracy, but with a diminished sense of responsibility for the care of the sick. It is true that many of our former ideas in pathology and the general conception of disease had to be discarded, which tended in itself to modify therapeutics, but the student too inexperienced to judge, discarded useful as well as useless knowledge. The brilliant results of serum treatment in a few diseases have increased the demand for specific forms of medication in all diseases. A skepticism has therefore arisen regarding all forms of treatment which did not coincide with this point of view. Much of the teaching to medical students transmitting the traditions of the profession to the coming generations, has reflected this same point of view, and greater stress has been laid upon multiplicity of diagnostic tests than upon the care of the patient and at times even the personality in the patient seems to have been forgotten. These statements apply more to internal medicine than to surgery. The whole of surgery with its enormous development is, in the final analysis, only a modified and highly mechanical form of specialized therapeutics which has bestowed incalculable benefit otherwise unattainable, but surgery is limited in its application and many of the morbid processes which destroy the usefulness and happiness of man today are far outside the domain of surgical interference.

The great development of medical schools and all branches of scientific

medicine has been rendered possible by the generosity of wealthy men. In the development and founding of laboratories it has been realized that the permanent staff are often performing unremunerative toil as far as outside income is concerned and must therefore be supported by endowment. The logical outcome has been that in order to obtain the best results, men must be found who are willing to give their whole time to anatomy, physiology, chemistry, and whatever other service can give no income from clinical sources. In the last few years the acme of the full-time idea has been reached, and the endowment of medical schools has been conditional on the agreement that physicians in the clinical practice of medicine and surgery should give their full time to the practice in the hospitals and to medical research, cutting themselves off as by an impassable wall, from those who may seek their special skill from the outside. It seems to the generous minded men of affairs who give the endowment, that they obtain a large return on their investment when they obtain for small salaries, men who in the outside world could earn four or five times as much as they agree to take in their restricted and secluded environment. In order to accept an honorable teaching position the sacrifice of 75 to 80 per cent of their earning power may be justly said to be a high devotion to a professional ideal.

That the transmission of the traditions of the profession, however, should be left to men cut off from full contact with the world, cut off from the puzzling questions of family life, from the questions of mental conflict of the individual, and from all those innumerable sources of influence on personality which make or break the success of medical care with the individual, looking therefore on medicine and surgery simply as the care of a morbid process with personality left out, should transmit the whole tradition of medicine to the succeeding generation, is neither good for the profession nor for the patients themselves. That this harm done to the highest ideals and the traditions of service to the sick was not acquiesced in by the mass of the profession has been evident from the fact that, in order to be sure of the fulfillment of the full-time idea each medical school to obtain its endowment, it is said, has had to sign an iron-clad agreement to carry out the full letter of the law of full-time service. The resistance of the profession has not been in vain to these limitations of

its ideals of service as shown by Columbia, the last university to which endowment has been given. This University has only agreed to make a trial of the full-time method and has not signed any further agreement. It is noticeable, moreover, that in the plans being brought forward on the medical side at least, it is frankly admitted in the development of the new scheme in Columbia that while the head of the department will be full time, there will be a number of partial-time assistants. These great endowments for scientific medicine have made the full-time man the main beneficiary and not the community which suffers, because the full-time man cannot develop into a practising physician and surgeon who typifies the highest ideals of the profession. It has increased the general tendency of, at least, rewarding the highest honors to those who develop their diagnostic acumen often at the expense of their ability to give curative care.

A Line of Cleavage

This uneven growth on the diagnostic side of medicine has produced two very marked results, one within, the other outside the profession. The one inside the profession has been the tremendous growth of the departments of health with the gradual encroachment on the field of medicine formerly peculiar to the general practitioner. So brilliant has been the success in preventing the spread of communicable diseases, that it has been realized that the best prevention lies in the early and complete care of all infectious diseases. Preventive medicine is turning its energies towards pneumonia, towards the venereal diseases and the health departments are now endeavoring to limit the spread of all communicable diseases by early and complete treatment. The early care of scarlet fever continued until the dangers of nephritis have passed has greatly diminished the number of nephritics in later life. The development in the dental profession and the appreciation by physicians of the dangers lurking in focal infections, have driven the realization home to every intelligent practitioner that the early, adequate care of many minor infections of today means the effective prevention of many crippling diseases of tomorrow. The purulent gums of today and the small dental abscesses, the annoying tonsillitis, only sufficient perhaps to make one drag wearily to work, if neglected, mean the arthritic cripple and the handicapped

cardiac or the chronic nephritic of no far distant date. In short, the enlargement of the field of usefulness of the health departments means that under sanction of the state and under the development of the prevention of disease, the state has begun to give therapeutic care where it believes it can improve upon the care usually given by the profession. The other reaction outside the profession has been the enormous increase in the various "pathies" and cults which the medical profession believes practice pseudo-medicine. Those with the petty ailments, with the various aches and pains, the unsolved problems left to one side by a busy practitioner, turn to these various cults because of the medical failure to relieve them. These cults could not exist if they did not have uneducated ignorance to play upon and medical mistakes to point to as their justification.

Costs in Group Practice

The great specialization of medicine with its increased necessity for laboratory diagnosis has unavoidably increased the expense necessary to establish accuracy of diagnosis. This has brought about the result that the very rich can afford modern medicine and the very poor have it given to them in institutions. The self-respecting families living on small incomes willing to pay for what they can afford, cannot obtain the first class medical care of today. This self-respecting group often obtains the best medical care, given through the generosity of individual members of the profession, but the price of medicine to the well-to-do pays for this, or else, the physician goes unpaid. The medical profession has no complaint to make on this score, but it recognizes the injustice to the large number of self-respecting families with small incomes.

It was evident in the report of the Insurance Committee of the American Medical Association two years ago, from sickness surveys made in the United States to ascertain definitely the amount of sickness in certain given localities, that there was always a noticeable number of sick who were not receiving adequate medical care or were not receiving any medical care, though seriously ill. It was further shown that among the poor, often the amount of medical care is in proportion to their incomes. In the dispensary investigations, a noticeable feature in the history of patients coming there for the first time, was the length of time they had allowed the illness to run

before they sought medical aid. All these facts showed a serious amount of uncared for sickness in this country. True it is, that no state has made a complete and perfect survey to ascertain with unquestioned accuracy how much sickness there is within its borders. For this reason a recent writer claims that no deductions are justifiable on any facts yet brought forward, because they are not complete for the whole nation or for any state. This is about equivalent to saying that unless a given patient shows a positive reaction to every laboratory test known today, the patient should go untreated for typhoid or syphilis.

Dissatisfaction in Rural Service

Another factor to be recognized is the diminution of medical practitioners in the rural districts and the crowding into the cities of the medical profession. Dr. Nicholl, Deputy Commissioner of Health, New York State, at the last meeting of the State Medical Society emphasized this as follows:

Thus from 1911 to 1919 the rural communities lost by removals and deaths 403 physicians, 13½ per cent, while the population has increased approximately 7 per cent. Twenty rural counties which in 1911 had 1,010 practising physicians, in 1919 had but 889, and those who remained had practised on an average of twenty-five years, and only 26 had been in practice for three years or less. In other words, death and dissatisfaction with rural practice have left that field to be covered by the middle-aged and old practitioners, with few or no recruits ready to take their places, when in the course of time they will have gone. Even the great improvement in the roads and in the general use of automobiles has not correspondingly increased the area which fewer physicians can cover, for in the past two and a half years eighty-three communities have appealed to the State Commissioner of Health to supply them with physicians. By advertising in medical journals, medical schools, and elsewhere, and by personal solicitation of possible candidates, the Department has been able to furnish thirty-six physicians; six communities have made arrangements with adjoining towns for medical services; two physicians have returned to their former practices; five communities have requested the Department to withdraw their applications, stating that they have grown tired of answering letters of applicants who, after ascertaining the local conditions, have been unwilling to take the practice. Thirty-two communities are, at last account, still without physicians. As far as it has been possible to ascertain the facts, the great majority of the localities listed contains a sufficient number of inhabitants who are able to pay for medical service to insure a living to the physician. In many of them a

physician may count upon better than an average professional income as it is generally estimated in the case of city practitioners. The history of former incumbents dead or moved away often denotes financial prosperity and the acquisition of a not inconsiderable personal property. But even if it should be granted that these localities do not offer sufficient advantages to induce qualified physicians to settle in them, what about the inhabitants who represent in the aggregate thousands of good American citizens?

It is evident, therefore, that, due to forces within and without the profession, the medical care obtainable is inadequately distributed or it is insufficient. At all events, the lack of medical care received has bred a restlessness to change the present order, hoping through some change that adequate medical care may be obtained. Some years ago, the remedy brought forward was that of Health Insurance, which has been indignantly and vigorously repudiated by the majority of the medical profession. This was brought forward shortly after the Workmen's Compensation Laws had gone on the statute books. The medical profession, not alive to what was then being done, found itself compelled to accept limited returns for a limited period of time for the surgical care of certain seriously injured workmen. Surgeons found they were being exploited both through limitation in the time during which care should be given to the seriously injured, and through the amount paid for the services rendered. The private insurance companies obtained a good business return for the work done but the medical profession was the one that bore the loss, and in many instances, felt itself clearly cheated out of just returns. There has been a gradual readjustment towards fairer dealing in these matters but when the insurance for sickness was brought forward, the profession throughout the country remembered their experience under the Workmen's Compensation Laws and would have none of it and would not even consider the case dispassionately.

Economic Arguments

The idea on which the request for health insurance was made was that of improved medical service to those who needed it and those who, under present conditions, did not obtain it. The answer of the medical profession to this plea was not a discussion of the medical service, it was an indignant refusal on economic grounds, although in New York the medical details were to be left for considera-

tion between the profession and the State and were not made part of the hard and fast organic law. In the last bill before the New York legislature, the entire decision of medical fees was left to the organized profession through the county societies to be settled between them and the state, with the proviso that no professional services could be given to the insured for less than was agreed upon between the profession and the state. Free choice was granted to the patient of any physician in the state. This insurance scheme was limited to those below a certain income. Beyond all question, sickness when it does come, is a calamity that bears very harshly on families with small incomes and tends invariably through loss of wages, to lower the standard of living of the afflicted family. Health insurance is so far the only scheme offered which gives the financial support to those who need it at the time they need it most and at the same time furnishes them adequate medical care. There is no question, as we have already said, that the care of minor ailments and the early care of all sickness is one of the most active and thorough going preventions against future disease. It is preventive medicine in its most practical form.

Health Insurance having been rejected, the Commissioner of Health of the State of New York, brought forward a year ago, a bill which would permit each county board of supervisors with the approval of the State Commissioner of Health, to establish in any county or part thereof, a health district and to appoint a board of health for each district and such Board of Health was to appoint a full time district health officer. The Board of Supervisors of the county were further allowed to establish community or health centers and in such, provide adequate hospitalization for any one needing hospital care; also clinics for out-patients; and also provide clinical, bacteriological, x-ray, and chemical laboratories auxiliary to the state laboratories, affording modern laboratory facilities needed in the diagnosis and treatment of disease, with service at a moderate charge or fee. They should provide a public health nursing service for all parts of the district, and proper medical supervision for school children and the facilities to enable practitioners to secure adequate treatment for all school children showing physical defects or disease. Provision should be made for headquarters for all other public health.

medical, nursing, and other public welfare agencies of the district wishing to utilize the same. The Board of Supervisors were to provide the funds for these centers and to appoint a Board of Managers of the Health Centers among whom two should be physicians and at least one should be a woman. The Board of Managers to exercise general management and control of the health center, and to make such rules and regulations as may be advised by the Medical Board as necessary for the medical and surgical care of the patients and for the study of the nature and cause of death in cases terminating fatally. Physicians and surgeons rendering services in the clinics should be properly compensated for their services and the Board of Managers is to see that such compensation is provided. Any physician sending a patient to the hospital can continue treatment of that patient if the patient so desires. The bill further provides for the construction and equipment of hospitals in such health centers, the state to pay one half the cost thereof and such payment not to exceed \$750 per bed established in such hospital and no greater hospitalization shall be constructed than one bed to each five hundred of the population affected. The State Health Department to have the power and control of inspection and standardization.

A Supplementary Service

Without further details this conception of Health Centers indicates that the State of New York realizes the inadequacy of medical care given throughout the state except to its wards receiving charity and to the wealthy who purchase it. The state officials seem to believe that the profession having been given the opportunity to form constructive suggestions and having refused to do so through the Committee of the State Medical Society, it is, therefore, necessary for the state to act through its State Health Departments and extend State care through the local action of county authorities. The two propositions, therefore, offered to the profession are community health centers—which is a modified form of state medicine—and health insurance—which is a mutual economic reconstruction of the costs of sickness by certain employees and their employers aided and controlled by the state and the profession, but the payment guaranteed by the state.

In comparing the relation of the profession to these two methods, in

the bill offered for health insurance the profession was given through the Counties Societies a just control of their remuneration. Under the Health Centers, the profession is under the control of Boards of Managers with medical representatives sitting thereon and these supervised and standardized by the state department of health.

Where Opposition Arose

The profession has always been interested in state control in the prevention of disease. It has always supported the health department in the development of state control. Only when the individual care of sickness has seemed to be interfered with has any antagonism arisen. The profession has, therefore, become accustomed to an increase of state authority through its state health department and naturally can appreciate with less resistance, changes brought about by this means. State medicine, as developed through local control and county districts, will bear less hardly on the profession, will be more fairly administered and will produce better results with less friction, than if state medicine were centralized in one central bureau and from there distributed over the state. Whether locally applied through counties, or centrally applied over the state, such development is plain state medicine, there is no other name for it and the reality must be squarely faced. If properly administered it can give the desired results, it can improve the health of the people, it can produce both preventive and therapeutic care, and by early care, can assure the prevention of future disease.

Under health insurance, as in the last bill introduced in New York State, it is possible for the profession through mutual constructive work with the state, to practise nearly as they are now doing in individual responsibility and to continue nearer than by any other scheme their present personal methods of practice. This opportunity, however, has definitely been repudiated by the profession. The future development of state medicine will mean further Federal development in control and supervision. One cannot contemplate federal control of medicine with any enthusiasm. A representative form of government such as ours and the federation of states such as is our Government, has not, up to this time, shown evidence that it can run and control by governmental ownership the railroads or properly administer med-

ical care to the men it was in honor bound to care for, the left over sick and wounded from the late war.

Public opinion demands a change in the present situation and is insistent that the medical profession should realize its responsibilities that with improved scientific knowledge it should give increased and better therapeutic care. So far the profession has answered this appeal in the negative on economic and all other grounds except that on which the appeal has been based.

It is very difficult for medical men to build up constructively any policy for work. Their whole life and their whole training is made up of broken thinking through constant change of subject in that thinking. Unable to obtain sufficient time to themselves to think connectedly and constructively, it is very difficult for medical men to think out any personal detail in any plan offered. Their opposition, therefore, to health insurance is easily understood. As the situation now stands, health insurance which would permit them to go on as they are, has been rejected. A form of partial state medicine through local application to soften its universal grip is offered instead. The profession is in the habit of thinking along the lines that the health centers offer and, at the present moment, the probability seems that the profession is tending that way. To many of us, however, health centers represent state medicine with all its bureaucratic control and limitations of individual development and personal service which, in the past, have made the practice of medicine an opportunity to follow a profession which permitted the practical application of high ideals. The highest development of any profession will, in my opinion, be injured by the deadening hand of bureaucratic direction.

What then should be the attitude of the profession towards health centers? The profession cannot without injury to itself always obstruct and oppose the desire and plans of the community for increased and better medical service. The continued passage of resolutions against all constructive plans offered will in the end result in any angry response by legislative action and the increased licensing of new pathies and cults. The most practical answer to all the unrest and demand for improved medical service is for the medical profession itself to formulate a constructive plan of better service given through concerted action by county

medical societies whereby adequate hospital facilities can be furnished for the medical, surgical and nursing care of the sick and which will give hospital opportunities to all physicians of each county. These hospi-

tals must be endowed with modern laboratory equipment for only with proper tools to work with, can improved medical service be provided in the rural districts. Manifestly, rural standards should be lower.

Public Health Association

THE Fiftieth Annual Meeting of the American Public Health Association was held in New York, November 14-18. Never in the history of public health has there been a more interesting or a more momentous gathering of health officials, better clinical demonstrations, a more important health exhibit, or a more inclusive program. It is impossible to do justice to the wide range of activities in a short comment.

The Jubilee Historical Volume, consisting of nineteen essays by leaders of public health, is a 480-page book edited by Dr. M. P. Ravenel for the occasion. An interesting souvenir of the occasion was the Stephen Smith Medallion, a bronze paper weight medal commemorative of Dr. Smith's notable service to public health, and Dr. Smith's own story of the early sanitary conditions in New York.

All the living past presidents of the Association but six are present at the meeting. They include: Dr. Stephen Smith, New York City; Dr. S. H. Durgin, Millbrook, Mass.; Dr. Peter H. Bryce, Ottawa, Ont.; Dr. Gardner T. Swarts, Providence, R. I.; Dr. Rudolph Hering, New York City; Dr. John F. Anderson, New Brunswick, N. J.; Dr. W. A. Evans, Chicago; Dr. Chas. J. Hastings, Toronto, Ont.; Dr. Lee K. Frankel, New York City; and Dr. Watson S. Rankin, Raleigh, N. C.

Incoming Officers

The Governing Council, at its Wednesday afternoon meeting elected the following officers and directors of the A. P. H. A. for the year 1921-22:

President—Allen J. McLaughlin, M. D., Assistant Surgeon General, U. S. Public Health Service.

Vice-Presidents—Haven Emerson, M.D., former Health Commissioner of New York City; Alfonso Pruneda, M.D., General Secretary, Superior Department of Health of Mexico; Royal S. Copeland, M.D., Health Commissioner of New York City.

Executive Secretary—A. W. Hedrich, C. P. H.

Treasurer—Roger I. Lee, M.D., Professor of Hygiene, Harvard University, Cambridge, Mass.

Governing Council

Terms Expiring 1922.—Dr. Chas. J. Hastings, Dr. Henry F. Vaughan, Dr. John A. Kappelman, Dr. John D. Robertson, Dr. Haven Emerson, Dr. Alfonso Pruneda, Dr. S. Josephine Baker, Dr. John F. Anderson, Dr. L. M. Powers, Dr. Robert H. Bishop, Dr. C. E. Terry, Dr. F. L. Hoffman, Dr. J. P. Kennedy, Dr. W. H. Peters, Prof. F. P. Gorham

Terms Expiring 1923.—Dr. R. L. Wilbur, Dr. John A. Ferrell, Dr. S. J. Crumbine, Dr. M. M. Seymour, Dr. Chas. J. Hatfield, Dr. Lee K. Frankel, Dr. W. S. Rankin, Dr. Juan Guiteras, Dr. Royal S. Copeland, Dr. E. C. Levy, Rowlett Payne, Dr. Don M. Griswold, John Vogelsson, Dr. A. J. McLaughlin, Dr. C. C. Slemmons.

Terms Expiring 1924.—Dr. Peter H. Bryce, Dr. W. A. Evans, Dr. M. P. Ravenel, Surg. Gen. H. S. Cumming, Dr. W. H. Park, Dr. C. V. Chapin, Dr. Roger G. Perkins, Dr. James O. Jordon, Dr. A. J. Douglas, Dr. D. B. Armstrong, Dr. C.-E. A. Winslow, Dr. George Ruhland, H. A. Whittaker, Dr. E. R. Kelley, Dr. F. F. Fronczak.

Michigan Health Meeting

Dr. R. M. Olin, commissioner, has announced a public health conference in Lansing, November 28 to December 2, in conjunction with the winter meeting of the Michigan Public Health Association. The state department of health has requested that every health officer and nurse in the state attend the meeting. Short courses of instruction and demonstrations will be given in problems of health administration and disease control. Among the speakers were: Dr. William H. Park, director of the Bureau of Laboratories, New York City; Dr. Haven Emerson, former health commissioner of New York City; Dr. Wade H. Frost, dean of the department of physiology and hygiene, Johns Hopkins University, Baltimore; Harriet Leete, R.N., American Child Hygiene Association; and Dr. Charles E. North, director of the North Public Health Bureau, New York City.

Infant Mortality as an Index of Progress

Improvement is Greatest Where Welfare Activities Receive Attention

By FLORENCE L. MCKAY, M.D., CHILDREN'S BUREAU, UNITED STATES DEPARTMENT OF LABOR, WASHINGTON, D. C.

THE infant mortality rate is a direct index of progress in the improvement of conditions which affect social welfare, including especially health, education, and standards of living and of morals. Enlightenment in these fields, if accompanied by active endeavor, will result in a marked saving in infant lives in any community, from the smallest hamlet to the largest nation. This should be attended by an equally marked improvement in infant vigor in general, for those very endeavors which by their resulting improved

we compare with other nations? What are the comparisons between states, and between municipalities? The tables and comments presented in this article will endeavor to answer these questions and to give a bird's eye view of variations in infant mortality rates.

International Comparisons

International interest in infant mortality rates is unusually keen at the close of a world war and in the wake of a world pestilence which have decreased to no inconsiderable degree the peoples of many nations. Table I, based upon the latest available vital statistics, indicates the relative position of twenty-one countries with regard to infant mortality rates.

TABLE I.—INFANT MORTALITY RATES FOR CERTAIN FOREIGN COUNTRIES AND THE UNITED STATES¹

Country and year—	Infant mortality rate
Chile (1919)	306
Hungary (1915)	264
Spain (1918)	183
Japan (1917)	173
Germany (1918)	154
Italy (1915)	147
Quebec (1917)	138
France (1919, 77 Depts.)	119
Finland (1917)	118
Scotland (1919)	102
Uruguay (1919)	101
Ontario (1918)	99
Denmark (1919)	92
England and Wales (1919)	89
Ireland (1919)	88
Switzerland (1918)	88
United States (Birth Reg. Area: 1919) ²	87
Netherlands (1919)	84
Sweden (1915)	76
Australia (1919)	69
Norway (1917)	54
New Zealand (1919)	45

1. Compiled from official figures as given in the Statistical Year Books of the various countries, or from the *Annuaire International de Statistique*. The figure given for the United States is taken from United States Bureau of the Census Birth Statistics, 1919. Latest figures available up to 1919.

2. Since this article went to press a rate of 86 in 1920 has been reported for the United States Birth Registration Area.

The table shows that New Zealand has the lowest rate—45 in 1919—and Chile the highest—306 in 1919. Thus in the same year, the rate in Chile is nearly seven times that of New Zealand. The next highest rate, which is 264 for Hungary, is a war rate and is unusually high for that country.

It will be noted that in 1919 the United States ranked sixth among nations, with a higher rate than New Zealand, Norway, Australia, Sweden,

and Switzerland. This is graphically portrayed by the infant mortality thermometer shown in Chart I.

In 1916 the United States was eleventh in rank. At that time, in addition to the countries named above, the rate in this country was also higher than that of England and Wales, Ireland, Scotland, and the Netherlands.

During the past decade most European countries from which vital statistics are available (Table II) have shown a steadily decreasing infant mortality rate, barring three inter-

Chart I.—The comparative showing of the United States, revised in accordance with the latest figures, is indicated. Much still remains to be done in improving conditions that affect infant welfare.

conditions reduce infant mortality must at the same time create possibilities for more perfect health.

With this in mind, the variations in infant mortality rates in groups of peoples, and comparisons between similar units are of special interest. For example, with the Nation as a unit, what are the indications of progress in our own country and how do

ruptions, the 1911 epidemic of summer diarrhea, the world war, and the 1918 epidemic of influenza.

In a notable article on "Infant Mortality in Europe" in the *International Journal of Public Health*, September, 1920, Knud Stouman brings out these encouraging facts: "When the war broke out the movement for the preservation of infant life was progressing rapidly, and it is gratifying that, even though the progress has been somewhat checked, most of the attained results have been maintained. The year 1915 was generally unfavorable, although less so than 1911, but 1916 is among the best years on record. Great Britain, Holland, and the Scandinavian countries have maintained the low infant mortality rates of the pre-war years.

a/ The figures in this table were taken from the statistical reports of the various countries when possible, or computed from figures from *Annuaire International de Statistique* Tome II (1917).

b/ These rates were computed from figures from *Annuaire International de Statistique* Tome V, (1911).

c/ Without the invaded departments.

The rates for France are somewhat higher, although not nearly so high as during the first decade of the century. Switzerland has succeeded in materially decreasing her infant mortality, while no impairment is remarked in Germany. No recent data are available for the countries of Eastern Europe."

Table II shows the annual rates since 1910 in countries for which statistics are available and indicates the general downward trend of most nations. The United States does not enter into comparison with other nations prior to the establishment of the birth registration area in 1915.

The 1919 infant mortality rate is 87 per one thousand live births. During the 1915-1919 period for which Census Bureau data are available, this rate in the United States has been reduced. The initial 1915 rate was 100. During the year 1916 it rose one point, to 101, but dropped the following year to 94. The rise in 1918 to 101 is attributable to the influenza epidemic. During the spring of that year the Children's Year Campaign was started, a war measure inaugurated by the Child Conservation Section of the Council of National Defense and the Federal Children's Bureau. Thousands of infants were weighed, measured and examined; public interest in the welfare of infants and children was aroused; many new welfare movements were initiated and those already existing were stimulated to increased activity. During the following year, 1919, the rate fell to 87, seven points below the 1917 figure. The 1920 rate, 86, is only slightly lower than that of 1919. Public in-

terest in infant welfare has continued to grow. It will be of interest to note whether there will be a continued reduction in the rates for 1921 proportionate to the increasing attention to the welfare of infants.

In this connection there is one important point that should not pass un-

noticed. The number of infant deaths in the first month is more than five times the number in the second month and sixteen times the number in the twelfth month, as is graphically shown in Chart 2.

This high mortality in the first weeks shows less appreciable reduction than that of the later months of the first year. The death rate for babies under one month of age fell from 44.4 in 1915 to 41.5 in 1919, a decrease of 2.9 for the four-year period, while the death rate for babies ages from one month to one year fell from 55.6 in 1915 to 45.2 in 1919, a decrease of 10.4 for the same period. Thus the decrease in infant mortality is largely a decrease in the deaths after the first few weeks of life. Statistics for 1919 show that 76.9 of the large number of deaths in the first month are due to natal and prenatal causes. These facts seem to indicate that growing infant welfare activities have reduced the number of deaths in the later months of the first year of life, when deaths are due chiefly to diseases of infancy, but that prenatal and maternity care have not been improved to the extent of effecting a corresponding decrease in

TABLE III.—DECLINE IN INFANT MORTALITY RATES FOR STATES IN THE BIRTH REGISTRATION AREA, 1915-1920

TABLE IV.—VARIATIONS IN INFANT MORTALITY RATES IN FAVORABLE AND UNFAVORABLE DISTRICTS IN THE SAME CITIES

City	Infant mortality rates		
	Favorable District	Unfavorable District	Favorable District
Baltimore, Md.	104	147	66
Cary, Ind.	126	141	84
Akron, O.	86	112	54
Jackson, Miss.	85	192	30
Metairie, La.	183	150	71
Providence, R.I.	97	114	71
New Bedford, Mass.	150	159	95
Manchester, N.H.	166	226	120
Concord, N.H.	134	271	50

deaths during the first month of life, which are largely due to natal and prenatal causes.

The fall from 1915 to 1919 is 13 points for a four-year period. If the decrease continues at this rate, it will take about fourteen years for our country to reach the present rate of 45 in New Zealand.

Mortality by States

Most of the States in the birth registration area show a similar downward trend of infant mortality rate, as may be noted from Table III.

All of the states of this area except Maryland, Minnesota, New Hampshire, and Vermont have state child hygiene bureaus or child welfare bureaus dealing with child hygiene. Except in the case of Kansas, Massachusetts, New York, and Ohio these bureaus have been established since 1915.

From the 1920 statistics issued by the United States Bureau of the Census it is found that among the cities having in 1920 a population of over ten thousand, only three have a rate as low as New Zealand.

Berkeley, Calif.	44
North Platte, Nebr.	39
Pasadena, Calif.	31

The six cities in the United States having the highest rates are as follows:

Dunmore, Pa.	229
Charleston, S. C.	209
Ogdensburg, N. Y.	190
Florence, S. C.	179
East Chicago, Ind.	174
Augusta, Me.	160

It will be noted that the highest municipal rate, 229 for Dunmore, Pa., is considerably lower than the highest rate among nations for 1919, —306 in Chile (Table I).

Comparing the rate of the birth registration area with municipal rates, it is found that the highest municipal rate is more than two and one-half the rate of the birth registration area, while the lowest municipal rate is less than three-eighths as high as the rate for the birth registration area. However, rates for municipalities for the period 1915-19 show a general downward trend, similar to that among nations and States, indicating general improvement in

conditions which affect child welfare.

The wide range in rates which is found in nations, States, and municipalities is apparently characteristic of different localities in the same city. Variations in rate in favorable and unfavorable localities in nine cities in which infant mortality studies have been made by the Children's Bureau are shown by Table IV.

Summary of Findings

Infant mortality rates show a gradual downward trend in nearly all countries for which statistics on this point can be obtained. New Zealand has the lowest rate, 45 per one thousand live births, while other countries have rates from one and one-fifth to nearly seven times higher than New Zealand.

In the United States birth registra-

tion area the rate has been reduced from 100 in 1915 to 86 in 1920. A downward trend is also found in individual states and municipalities. This decrease is less marked for the first month of life, when the chief causes of death are natal and prenatal, and more marked in the later months, when diseases of infancy are the main causes, thus indicating an increasing attention to infant welfare activities without a corresponding increase in prenatal and maternity care.

The gradually decreasing infant mortality rate of most of that portion of the world from which statistics are available is indicative of progress, but the figures show that much still remains to be done in improving conditions which affect infant welfare as a field in which the right measures may reasonably hope to prevail.

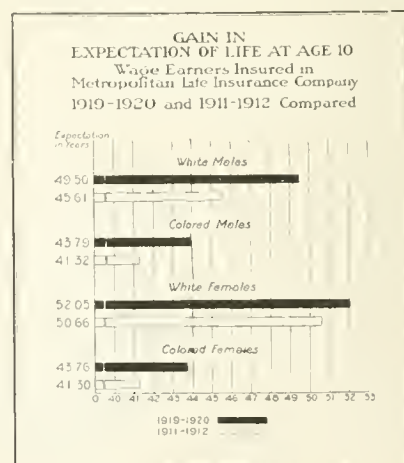

Life Span Lengthened

THERE is probably no more convincing instance of the beneficial effect of a well considered campaign of health education and of health service than that afforded by the mortality experience of the policyholders of the Industrial Department of the Metropolitan Life Insurance Company. In 1910, this company put into operation a plan, the purpose of which was to reduce the death rate among insured wage-earners. From year to year, the program was extended and now embraces in excess of thirteen million men, women and children of the wage working population who are policyholders. At the end of ten years, the death rate had been reduced more than one-fifth. A total of 38,000 fewer deaths occurred in 1920 than if the 1911 mortality rate had prevailed.

But, there is an even more instructive measure of the value of public health work than the reduction of the death rate. It is the added duration of life of the insured groups as measured by life-tables. At the beginning of the campaign, white males at age 10 could expect to live 45.6 additional years. At the end of the decade, this expectation was increased to 49.5 years. This means a clear gain of nearly four years for every insured white male. *There is no record of a like increase in the life span, within so short a period, in the whole literature of public health work.*

The white female policyholders did not show so great a gain as the white males.

These figures are after all the ultimate test of the value of health work. They show at a glance what the effects are in terms of a lengthened life-span. A year added to the duration of life of every person at age ten is a very tangible addition to the assets of a country; for the ages beyond ten are years of productivity. In connection with insured white males, the increase is virtually four years per person. If such an increase in expectation of life could be made general for the entire white male population of the United States, the gain to the present generation in this country would be stupendous. This is the lesson which must be drawn from the health work of the company among its members. The following chart shows graphically the figures for each of the color and sex groups. The favorable experience was between the ages of forty to sixty.

Food Values in Canned Meats

BY GEORGE W. TRAINOR, ARMOUR & Co., CHICAGO

THE canning industry is little over one hundred years old. Late in the Eighteenth Century, Nicholas Appert, a Frenchman, began a series of food experiments

All meats used for canning are carefully inspected by Government employees throughout the entire process from killing to canning.

with the object of finding an improved method of preserving them. His vast experience in dealing with foods proved to be of great value to him in his experiments, which resulted in his successfully preserving various kinds of meats, vegetables, fruits, etc. These he kept intact for several years, and upon opening them found them to be as appetizing as freshly prepared products.

Prior to this time foods that were to be kept any length of time were pickled, dried, smoked, or preserved in sugar, methods which left much to be desired, for they caused waste, spoilage, loss of flavor, and color, etc.

Appert¹ published the results of his experiments in 1810, and in appreciation the French Government awarded him a prize of twelve thousand francs, at the same time bestowing upon him the title of "Father of the Art of Canning." As he gives it himself, Appert's method of preserving consisted of:

- (1) Inclosing in the bottle or jar the substances to be preserved.
- (2) Corking these different vessels with the greatest care, because suc-

Stability and general well being fluctuate according to nutritional conditions, the regulation of physiologically associated organs being almost wholly a matter of bodily chemistry.

Likewise, the welfare of nations is bound up with the regularity and the even distribution of the food supply. The provision which first conserved foods in seasons of abundance against periods of dearth marked a fundamental condition of progressive development.

Professor L. Bolk's thesis before the Eugenics Congress was that the changes in metabolic processes incidental to the transition from a vegetable to an omnivorous diet sufficiently account for the transformation of the order of anthropoid apes into the Genus homo. The whole subject is of the greatest interest and importance.

cess depends chiefly on thoroughness in closing.

(3) Submitting these substances, thus enclosed, to the action of boiling water in a water bath for more or less time, according to their nature.

(4) Removing the bottles from the water bath at the time prescribed.

This method includes all the funda-

mental principles of modern canning.

Appert laid special stress upon the necessity of cleanliness, freshness of products, expedition in handling, and upon great care being exercised to have containers air tight. He says that sterilization is invariable if the above details and correct time of heating are observed. He did not know why foods canned in this manner retained their freshness, but ascribed it to heating with the exclusion of outside air.

We now know that there are micro-organisms in all foods, in the air, water, containers, etc., which cause decomposition and spoilage; also, that sufficient heat kills them and, if the jar or can is air tight, those from without are excluded, thus causing the contents to become and to remain sterile.

Soon after Appert's work was published, the great usefulness and advantages of such a method were seen, and commercial canning began about 1820. About this time tin cans began to be used instead of glass—hence the name, "canning."

This industry has advanced most rapidly in the United States—in fact the estimated value of canned foods in this country alone was more than four hundred million dollars in 1919.

Methods of Canning

Meats, which form such a highly important part of the human diet,

Vacuum machine for drawing the air out of the cans. While in this condition a drop of solder is put on the vent hole with an electric hot-point iron.

1. The Art of Preserving Animal and Vegetable Substances for Many Years, by Nicholas Appert, translated by K. G. Bitting.

are more perishable than any other food products, and, of all methods of preserving them, canning is in many ways the most satisfactory. In most cases meat to be canned is parboiled or cooked for a short time to remove the moisture and blood. It is then conveyed to trimming tables, where all skin, gristle, etc., are carefully cut off. From here it goes to large machines which stuff or compress it into cans, or, as in the case of some products, such as tongue, it is put in the cans by hand. After each can is weighed, a closing or capping machine closes it, leaving a small vent hole in the cap through which the air is drawn out. This latter operation is performed by a vacuum machine which consists of an enclosed circular chamber with a revolving table in it. The cans are placed in this machine, the air drawn out, and while in this condition a drop of solder is placed on the vent hole with an electrically heated point. After coming out of the vacuum, the cans are thoroughly inspected for leaks, and, if any are found, they are repaired at once. Next comes sterilizing, or processing. The cans are placed in large iron retorts, or autoclaves, and kept there at a constant temperature for a definite length of time, according to the product being sterilized.

In the early stages of the industry, all processings was done in water. Later salt water, calcium chlorid water, and oil baths were used to obtain a higher temperature than could be reached with water alone. At the present time most processing is done in steam retorts, or autoclaves. It has been found that most canned products are more palatable if heated at a high temperature for

Temperature and pressure controlled retorts for the sterilization of canned meats.

a short period of time, than at a low temperature for a longer time, although this is not true in all cases. Late types of retorts are equipped with controls for pressure, temperature and time, and there is no danger of under or over-sterilizing. After this operation the cans are labeled and packed, that is, they are packed after having been inspected again and all imperfect cans have been thrown out.

Precision in Details

To insure satisfactory results in the process of canning, many details must be carefully observed, a few of the most important of which are:

- (1) The use of fresh raw products, for the quality of the finished product depends, of course, upon the grade and condition of the meat canned.
- (2) Expedition in handling.

(3) Cleanliness of all containers, machinery, workmen, etc.

(4) The use of air tight and well vacuumed cans.

(5) Correct time and temperature of sterilization.

If the above precautions are taken in canning meats, the finished products are bound to be the purest and most sanitary of foods.

Commercially canned meats are inspected by government employees from the time the animals are killed until the cans are shipped, and the Government's stamp of approval is on every can, a fact which protects the consumer against diseased or unfit meat.

In many places throughout the world where fresh meats can not be obtained in good condition, also where none are to be had at all, canned meats are a necessity, and, even where the supply of the fresh product is unlimited, they are a great convenience. Undoubtedly, were it not for the widespread activity of the canning industry, it would be impossible for the world to enjoy the almost unlimited variety it now does in the way of meats, fish, fowl, etc.

The process of preparing and sterilizing canned meats is such that all the natural flavor and food value of the fresh product is retained and the perfect edibility of the contents insured.

A Real Conservation

Aside from their food value, canned meats are economical, in that they can be shipped any place without refrigeration and held indefinitely in ordinary storage. They remain good as long as the can is solid. Most canned meats are ready to serve

Sanitary closing machine which puts the top on the can without the use of acid or solder.

A daily inspection of the hands of all employees who handle the meats is required.

with little or no preparation. Their economic advantages are well set forth in the *Daily Express* of February 21, 1917, as follows:

Lord Derenport's meat ration of two and a half pounds is represented by less than one pound of corned beef, which can be bought at about one-third of the price of its equiva-

lent in butcher's beef. Corned beef is a most economical form of beef ration, both as regards shipping space and cost to the consumer. Corned beef can travel as general cargo, while it occupies only one-third of the space required by chilled or frozen meat. Not only does it effect a great saving of freight, but, seeing that it is already cooked, no fuel is required.

There has been a great deal of prejudice against canned meats and canned foods in general, a fact which in great part may be attributed to the publication of sensational newspaper stories about people becoming poisoned through eating canned goods. Many of these have been proved to have no foundation. The process of their manufacture insures their being the safest foods, the routine care which is given all foods being sufficient to eliminate the danger of their being unfit for human consumption.

American Child Hygiene Association

THE American Child Hygiene Association was organized (under the name, The American Association for Study and Prevention of Infant Mortality) at New Haven in 1909, and during the first week of November, 1921, it returned to its birthplace as a very healthy and highly developed youngster. The last two years under the leadership of Dr. Philip Van Ingen and Dr. H. L. K. Shaw have seen a rapid development in the work of the organization, which now has permanent offices in Baltimore, employs a general director, an assistant general director and a director of field work, has an annual budget of some \$65,000 a year, and publishes its own magazine, *Mother and Child*.

The address of Dr. H. L. K. Shaw,¹ the president for the New Haven meeting, presented an admirable analysis of the history of the child hygiene movement in Europe and in America. He reported that thirty-eight cities and forty-five states now have special departments of child hygiene and recorded the remarkable results which have been accomplished in the reduction of infant mortality during the past decade. In 1910 the infant mortality rate was 149 in the United States and 109 in England, while in 1920 the respective rates were 86 and 80.

One of the most notable tendencies

of the meeting was the broadening out of the campaign to include the whole field of child health and the enlistment in the directorate and in the program of a large number of non-medical workers. The principal address at the evening public session was delivered by Miss Grace Abbott, the chief of the Children's Bureau in Washington, who made an earnest plea for the maintenance of the resources of child welfare organizations of all types to meet the crisis of the coming winter. A very large part of the program of the sectional meetings was devoted to such problems as the coordination of various types of child health work, education of the public in the needs of child hygiene, and the problems and opportunities of lay directors of private organizations working in this field.

Its Place in The Program

In regard to the question of coordination of activities, Dr. Haven Emerson made an effective presentation of the admirable work accomplished by the Babies Welfare Federation and the new Harlem Health Center in New York, and at a later session some of the more knotty problems were debated in detail. There is as yet no agreement on the question whether child hygiene work should be organized as part of a program for child welfare or as a part of the program for community health—on the question whether public health

nursing in a city or state health department should constitute an independent bureau, or should be distributed in various other divisions—or on the question how the development of a state medical program of child welfare can be justly and wisely coordinated with the work of the private practitioner of medicine. Dr. Champion of Massachusetts made a strong plea for a division of child hygiene under a state department of health with purely advisory functions, and Miss Margaret K. Stack of Connecticut presented effective arguments for the organization of public health nursing work in a separate division of nursing, but the final answer to such questions is still far to seek.

In the discussion of health education Mrs. Arnold Gesell presented a brilliant and stimulating discussion of the weaknesses of public health education at the present day and the fundamental reactions of the child mind upon which such education should be based. A special round table discussion was devoted to rural problems, another to the special problems of directors of divisions of child hygiene, and one general session was devoted to the child of pre-school age.

The medical session held at the New Haven Hospital was of very special interest. Dr. Robert B. Osgood of Boston, contributed a convincing presentation of the evidence in regard to the effect of faulty posture on alimentation and elimination

¹ The papers by Dr. Shaw and Dr. Osgood will appear in early issues of THE NATION'S HEALTH.

and its association with joint symptoms, cerebral symptoms, asthenia and underweight. Dr. E. A. Park of the Yale School of Medicine summarized the evidence in regard to the effect of sunlight and ultraviolet rays in curing rickets and presented striking new data in regard to this problem; and Dr. F. G. Blake, of the Yale School of Medicine discussed measles and its prevention and de-

scribed the very promising experiments carried on in his laboratory looking toward the preparation of a serum for this disease.

The meetings at New Haven were among the most successful in the history of the organization and the acceptance of the presidency for 1921-22 by Mr. Herbert Hoover is a testimony to the unique importance of its work.

introduced on November 15, 1921, a bill (S. 2727) to amend section 19 of the copyright law, so that hereafter the title page date must tell the truth. The proposed amendment is as follows (the new, or added, part is in italics):

Sec. 19. That the notice of copyright shall be applied, in the case of a book or other printed publication, upon its title page or the page immediately following. *Provided, That wherever a date of publication or of issue appears, the notice of copyright shall also appear, or if a periodical either upon the title page or upon the first page of text of each separate number or under the title heading, or if a musical work either upon its title page or upon the first page of music: Provided, that one notice of copyright in each volume or in each number of a newspaper or periodical published shall suffice, except as herein provided.*

The bill has been referred to the Committee on Patents, whose personnel is as follows: Hiram W. Johnson, California (Chairman); George W. Norris, Nebraska; Frank B. Brandegee, Connecticut; Richard P. Ernst, Kentucky; Ellison D. Smith, South Carolina; A. Owsley Stanley, Kentucky; Edwin S. Broussard, Louisiana.

These gentlemen can be reached by addressing communications to Senate Office Building, Washington, D. C.

How long a bill will remain in committee ordinarily is an unanswerable question. If, however, the physicians of the country grasp this opportunity to advocate an amendment which is founded on right, an early hearing will be obtained. The proposed legislation, if written into the law, will not harm any honest man. It is of constructive, not destructive character. Members of the medical profession now have an opportunity to aid in the correction of a long-standing abuse. Will they rise to the occasion?

Social Hygiene and Eugenics

In recognition of the second International Congress on Eugenics, held in New York during September, the July issue of *Social Hygiene* is devoted largely to the consideration of eugenic questions. Among the articles appearing in this issue are the following: "The Distribution of Wealth, as a Eugenist Sees It," by R. H. Johnson; "Some Disgenical Effects of the War in Italy," by Marcello Boldrino; "Eugenics in the Central Empires since 1914," by Prof. Geza Von Hoffman; and "The Sins of Industry Against the Race," by Herman Lundborg.

A Defect in the Copyright Law

By JAMES MOORES BALL, M.D., ST. LOUIS, MO.

OUR present copyright law, which contains many excellent features, was introduced as "An Act to Amend and Consolidate the Acts Respecting Copyright." It was approved March 4, 1909, and went into effect July 1, 1909. It has been amended three times: March 2, 1913; March 28, 1914; and December 18, 1919.

Under its provisions he who first sends to the register of copyrights, in care of the Librarian of Congress, Washington, D. C., two printed or typewritten copies of a proposed publication, enclosing therewith the legal fee, is granted the copyright whether or not he is the author of the proposed work. This is the expeditious, and possibly the only feasible way to transact a vast volume of business. In case of fraud, the aggrieved party can take his case to court with a chance for justice.

An Inherent Defect

The law has one defect, in that it does not prohibit the printing of a date on the title page different from that of the copyright.

Section 19 of the original Act says: "That the notice of copyright shall be applied, in the case of a book or other publication, upon its title page or the page immediately following." It does not say that the title page, if it bears any date, shall bear an honest date, *viz.*: that of the year of granting the copyright.

Owing to the existence of this loophole, a few unscrupulous publishers are able to dispose of their left over wares of an earlier vintage. The busy physician, looking at a title page dated 1921, naturally would think that he is ordering an up-to-date volume. Some salesmen will go so far as to say, "This is the latest edition." Of course, although printed five years before (as the copyright date shows), it is "the latest edi-

tion." The manuscript for a new edition, on which the author has worked for many months, rests peacefully in his bedroom, within easy reach; so that any new idea, arriving possibly at the time of the crowing of the cock, or at the unholy hour when the milkman treads his weary way, may be set down.

The title page date is a fraud, unless it is the same as that of the copyright. The copyright date always should be looked for. It has to tell the truth. Such is the law. It is to be regretted that there is not another law making it a crime for a publisher to use on the title page a date different from that of the copyright.

And what recourse has the author, who, having permitted his publisher to secure the copyright, finds that the child of his (the author's) brain is placed in the class of illegitimates? At present, none.

The author's friends, not understanding the sharp methods of a publisher, may condemn him without a hearing. The author, as recently occurred to our own discomfiture, may learn of the spurious edition only when members of his profession, residing in distant cities, write letters of condemnation so filled with sulphur and brimstone as to cause the recipient to wonder that the mail bags did not burn *en route*.

Wherefore, the copyright law needs to be amended so that, if the title page bears a date, it must be an honest one, in that that of the year of the granting of the copyright.

The writer proposes (D.V.) to see that the law is amended. He asks that the organized medical profession, the various societies of allied sciences, and all honest publishers, aid in the movement.

At the writer's request, the Honorable Selden P. Spencer, junior United States Senator from Missouri,

A Summary of Recent Health Legislation

BY DOROTHY KETCHAM, CHICAGO

THE publication of the various state laws enacted during the legislative sessions of 1921 is not yet complete. In consideration of the great mass of health and safety legislation enacted, it will be possible here only to summarize briefly and by topics those provisions which have been enacted in the various states. Only the legislation of 1921 has been included, so that reference will be made to the chapter or page of the session laws, acts, or resolves. The following states have to date published their session laws, so that a more detailed summary has been made of their provisions: Arizona, Hawaii, Idaho, Illinois, Indiana, Kansas, Massachusetts, Minnesota, Nevada, North Carolina, Oregon, South Dakota, Utah, Vermont and Washington. In the remaining states legislation is cited by title: Arkansas, California, Colorado, Connecticut, Delaware, Florida, Georgia, Maine, Michigan, Montana, Nebraska, New Hampshire, New Mexico, New Jersey, New York, North Dakota, Ohio, Oklahoma, Pennsylvania, Rhode Island, South Carolina, Tennessee, Texas, West Virginia, Wisconsin and Wyoming. *The Index to State Legislation, 1921*, a bulletin of the Public Affairs Information Service, published September 17, 1921, is issued as a basis for discussion.

Abattoirs.—California C. 732 provides for the sanitary inspection of slaughter houses and the inspection of animals or meats intended for human consumption. Wisconsin has prohibited the business of slaughtering on the banks of any stream or in any place where a slaughter house is not provided.

Anthrax.—Oklahoma C. 216 makes an appropriation for prevention and eradication of anthrax among the other contagious and infectious diseases of animals.

Baking Industry.—California C. 701, North Carolina C. 173, and Texas C. 63 regulate and prescribe the sanitation of buildings, the character of baking products, the cleanliness of receptacles, etc. The North Carolina law is herein summarized:

Every room or other place occupied or used as a bakery for the preparation, production, storage, or display of bakery products intended for sale for human consumption, shall be clean, properly lighted, and ventilated. Floors, walls, and ceilings are

to be kept and maintained in clean and sanitary condition, and all openings are to be screened, adequate drainage and suitable wash sinks to be provided. Toilets are to be well ventilated and kept in sanitary condition. Tables, shelves, and implements to be cleaned daily and refuse removed daily. Work rooms are not to be used as sleeping or living rooms. Employees are not to sit or lie on the tables. Hands and arms to be washed thoroughly before preparing or mixing ingredients. Tobacco is not to be used in any form. Adulterants and stale products are not to be sold.

Barbers.—Minnesota, C. 424, Missouri, S. B. 318, and Texas, C. 79, have created boards of barbers' examiners to license barbers and to prescribe rules and regulations to prevent the spread of infectious or contagious diseases. Texas includes beauty shops in "those engaged in the business, occupation or employment of caring for, dressing, adorning, and beautifying the human hair, face, scalp, hands, and skin."

Blind and Blindness.—Missouri H. B. 70 has provided pensions for the adult blind under certain restrictions of residence and dependency. Arkansas No. 525, Connecticut C. 236, and North Carolina C. 152 provide for the care, maintenance and instruction of children too small or backward to enter the state school for the blind; for the education of certain groups in their homes; and provides aid for the necessary expenses of blind students in universities, colleges, and conservatories of music.

Connecticut C. 242, Delaware C. 42, Idaho C. 233, Missouri S. B. 98, Nevada C. 230, Oklahoma C. 4, and Texas C. 89, prescribe the use of prophylactic solution in the eyes of the newborn and the reporting of its use, or the development of inflammation, to the boards of health.

Canning Industry.—Idaho C. 223, p. 511, makes the following regulation of the canning industry:

All matters and things relating to the sanitation of factories or establishments, and cold storage plants in which foods and food products of vegetables, fruits, meats, or by-products thereof, are manufactured, evaporated, dehydrated, preserved, pickled, handled, kept in cold storage, or placed in jars of tin, glass, wood fiber, or other containers, are under the supervision of the Department of Public Welfare.

All rooms in which the manufacturing is carried on are to be provided with smooth water-tight floors

which can be cleaned, and all walls, partitions, and ceilings are to be cleaned, painted, or whitewashed, and kept in sanitary condition, and insaniary equipment is to be replaced with suitable equipment and material. The rooms are to be properly ventilated, free from odors, and provided with suitable cuspidors. All outer windows and ventilators are to be screened against flies and insects. All utensils and machines used in the process of manufacture of food products are to be thoroughly cleaned before and after being used, and surroundings to be kept in a clean and sanitary condition, the waste not to accumulate. Hot and cold water is to be provided and only pure water and ice are to be used in the preparation of food products. Toilet rooms are to be provided.

Children.—Arizona C. 53, and Delaware C. 63, establish state child welfare boards. Connecticut by C. 383 provides for the licensing of boarding houses for children by the new bureau of child welfare; by C. 381 regulates county homes for children; and by C. 81 amends a previous law by increasing the penalty for cruelty to persons—children. Connecticut C. 265, has also provided for the physical and mental examination of children before their commitment to a county temporary home. Missouri S. B. 224 provides for the licensing, regulation and supervision of boarding houses for infants or children and the placing of children. In South Dakota C. 112 provides for child welfare boards in each county, consisting of two women appointed by the State Child Welfare Commission, the county superintendent of schools, the county superintendent of health and the county judge. These people make such visits as the state commission requires, and they act in a general advisory capacity to the county and municipal authorities dealing with questions of dependency, delinquency, and social conditions. Massachusetts C. 360 presents the school term and curriculum, including in enumerated topics the teaching of physiology and hygiene, indoor and outdoor games, athletic exercises and an explanation of the effect of alcoholics, narcotics, etc. Vermont, No. 217, places upon the Board of Charities and probation the duty of furnishing medical and surgical aid to physically defective and crippled children, if such parents are willing but unable to furnish the necessary treatment.

Chiropractic.—Arizona C. 118, Ar-

kansas No. 485, Georgia H. B. 86, New Hampshire C. 150, New Jersey C. 136, New Mexico S. B. 101, Oklahoma C. 7, and South Dakota C. 143, authorize and regulate the practice of chiropractics. New Jersey abolished the State Board of Chiropractors, and added a chiropractor to the State Board of Medical Examiners, which is given power to license chiropractors or other special methods of healing.

Cleaning and Dyeing Industry.—Indiana, by C. 172, has provided that no room or structure shall be used for the business of dry cleaning or dry dyeing, until application for permission is filed and approved by the State fire marshal. On such application the State Fire Marshal or his deputies or assistants, is to inspect the premises before issuing permits. The permits are to be displayed by the establishments.

The rooms are to be of fire-resisting design and construction, the buildings not more than one story in height and without cellar or open space below the first floor. Specifications are made for walls and ventilation, for the protection of steam pipes, fire extinguishers and settling tanks, the location of engines and lighting and heating equipment.

Minnesota, by C. 459, has enacted a law quite similar to that of Indiana. Dry cleaning and dyeing establishments are to be licensed by the State Fire Marshal after application to do so has been filed with and approved by him. Permits are not to be issued for more than a year and may be refused, suspended, or revoked. All buildings must be fireproof, not exceeding three stories in height, and shall be without basement, cellar, or open space below the ground floor, the workroom where all dry cleaning is done is to be located on the ground floor. Construction is to be of stone, cement, etc., without sewer connection, and a cement pit is to be provided for liquids. The ventilating system prescribed is to be such as will completely change the air every five minutes.

Skylights and windows are to be of wired glass set in steel frames, stationary, and for lighting purposes only. All windows to close automatically at 120 degrees F., and are to be covered with wire screens. Fire extinguishers are to be provided and steam or hot water pipes protected. The machinery is to be specially constructed, as are heating, lighting, storage tanks, underground tanks, pumps, with separate buildings for gas.

Cold Storage.—New Jersey C. 71 prohibits the alteration or destruction of labels on packages showing the time food was placed in cold storage. Wisconsin C. 520 provides for the branding of cold storage products.

Examination and Criminal Identification.—Nebraska No. 482, Ohio S. B. 53, and South Dakota C. 186 provide means of criminal identification by authorizing the taking and preservation of photographs, measurements, etc. Pennsylvania No. 208 requires that persons sentenced to penal institutions are to be examined physically and mentally and in proper cases may be segregated.

Dairy Industry.—Arizona C. 93 and Idaho C. 188 regulate the sale of imported meats, poultry, eggs, and butter, requiring the same to be labeled. Florida C. 8534, Kansas C. 276, Minnesota C. 495, Nevada C. 167, North Carolina C. 169, and Wyoming C. 85 regulate the sale and adulteration of milk, cream, ice cream, etc., establishing standards and requiring licenses. Minnesota C. 306 requires common carriers to establish and maintain clean and sanitary storage rooms for the reception of milk, which are to be licensed and inspected, Missouri H. B. 469 prohibits unfair discrimination in the purchase of milk, cream, butterfat, butter, eggs, and poultry.

Day Nurseries.—In Oregon C. 46 a day nursery is defined as an institution "in which are commonly received at one time three or more children not of common parentage, under the age of fourteen years" for periods of from four to twelve hours. The State Board of Health is to grant licenses for their conduct on sworn application containing required information, all licenses to expire at the end of a year. The State Board of Health is to make rules and regulations concerning the licensing and conduct of day nurseries and may by its agents inspect the same at any time, each to be inspected and visited at least once a year. On thirty days' notice the license may be revoked "if in its judgment public interest so demands."

Defective Children.—In Connecticut, by C. 30, any town, city, or borough may enact or amend charter provisions providing for the medical care and treatment of children of compulsory school age whose education is retarded by reason of physical defects, and by C. 335 the State Board of Education is to appoint a director of special education and standards to encourage special provision for children below standard phys-

ically or mentally. Rhode Island C. 2027 regulates the granting of working permits to backward children.

Defectives.—Arizona S. C. R. 3 requests the National Committee on Mental Hygiene to conduct a mental deficiency survey of all state, county and city institutions as well as the public schools.

Dental Hygiene.—California C. 412 establishes a division of dental hygiene for children under the direction of the state board of health.

Eggs.—The inspection and certification of imported eggs and egg products for human consumption is provided by California.

Feeble-Minded.—South Dakota C. 232 adopted the uniform act for the extradition of persons of unsound mind and also created (C. 235), a state commission for the control of the feeble-minded. The purpose of the Act as stated is "that all feeble-minded persons resident within the state shall become wards of the state and shall be kept segregated to the end that they shall not produce their kind." The Commission has power to promulgate rules and regulations and survey institutions.

Food and Food Handlers.—South Dakota C. 242 provides that every building, room, basement, inclosure or premises, occupied, used, or maintained as a bakery, confectionery, cannery, etc., for the preparation, manufacture, packing, storage, sale or distribution of any food intended for sale is to be properly and adequately lighted, drained, plumbed, and ventilated "and shall be conducted with strict regard to the influence of such conditions upon the health of the employees, operatives, clerks, or other persons therein employed and the purity and wholesomeness of food therein produced."

Floors, side walls, ceilings, furniture, receptacles, implements and machinery of every such establishment or place where food is produced, and all vehicles, etc., shall at no time be kept or permitted to remain in an unclean, unhealthful, and insanitary condition, to be of tile, etc., doors and windows to be screened, and toilet rooms and cuspidors provided.

Pennsylvania No. 169 requires employees handling food to have and produce doctors' certificates, while Texas C. 66 states that persons, firms, or corporations which operate or conduct hotels, cafés, restaurants, dining cars or other public eating places, bakeries or meat markets, shall not work, employ or keep in their employ any person who is affected with any contagious or infectious disease.

Fruit Industry.—California C. 719 amends an earlier law which relates to the establishment of standards and standard packages for certain fruits, nuts and vegetables, to prevent deception in packing and to provide for their certification presenting penalties for violation.

Hospitals.—Connecticut C. 82 passed a general law concerning the defrauding of general hospitals, and Maine C. 112 to control the establishment of sanatoriums and hospitals for infectious and contagious diseases within the populous districts of cities and towns. Idaho C. 57 and Missouri S. B. 152 regulate the licensing and inspection of maternity hospitals. State, city, and county institutions are specifically exempt in Missouri. Texas C. 76 requires an annual license and fee from every individual, firm, association, or corporation owning, keeping, conducting, or managing an institution, a home for the boarding or sheltering of infant children, or so-called "Baby Farm" or any lying-in hospital, hospital ward, maternity home, or other place for the reception, care and treatment of pregnant women, charging a fee or receiving or expecting compensation.

Hotels.—North Carolina C. 186 provides for the sanitary inspection and conduct of hotels and restaurants: In all cities, towns, or villages where a system of waterworks and sewerage is maintained for public use, every hotel therein accessible to water main and sewer main shall be equipped within six months after passage of Act with water closets. Lights are to be provided in water closets and doors to windows are to be screened against flies. Such fly paper and fly traps are to be used as "necessary to keep their restaurant, kitchen, and dining room reasonably free from flies." Beds and furniture are to be kept free from vermin. Clean towels are to be supplied each guest and tableware and the kitchen utensils to be washed after using.

Housing.—California C. 354 passed the State Housing Act which regulates the erection, construction, reconstruction, moving, alteration, maintenance, use, and occupancy of tenement houses, hotels, and dwelling houses in incorporated towns, cities, and counties. Iowa H. file 794 regulates the issue of building permits by a building commission or department. Indiana, by amending an existing law, created a new division in the State Board of Health, the Division of Housing, with an appropriation of \$15,000.

Ice Cream Industry.—Florida C. 8534, Kansas H. B. 199, North Carolina C. 169, and Ohio S. B. 105 license and regulate the sanitary conditions of the ice cream manufacturing concerns, the cleansing of utensils, the method of obtaining tests and other sanitary standards are prescribed.

Industrial Cripples.—Arizona C. 78, California C. 758, Idaho C. 441, Indiana C. 204, Massachusetts C. 462, Michigan No. 211, Missouri H. B. 494, New Mexico H. B. 161, North Carolina C. 172, Ohio H. B. 218, Pennsylvania No. 4, Rhode Island 2031, Utah C. 97, Wisconsin C. 534, and Wyoming C. 109 and 110, accepted the benefits of the Vocational Education Act of the Federal Government relating to persons disabled in industry. Plans for cooperation between the state and federal boards are to be formulated, courses are to be provided and training supervised. North Carolina specifies that not more than ten dollars a week is to be paid to any one person. Georgia, Iowa, Maine, Montana, and West Virginia also by legislative enactment adopted the provisions of the law, some sanctioning the action of the governor already accepting same. Minnesota and Nevada accepted in 1919, Alabama, New Jersey, New York, North Carolina and South Dakota in 1920

Juvenile Delinquents.—Nebraska H. roll No. 84 provides for a clinical psychologist under the supervision of the Board of Control, and Wyoming C. 159 for the mental examination of all juvenile delinquents committed to the state institutions.

Maternity Benefits.—Minnesota C. 392 through the State Board of Health plans to give advice and instruction to expectant mothers during pregnancy. New Hampshire C. 151 and New York C. 420 provide for the protection of the public health by prenatal, maternity, and infant care.

Meat.—Arizona C. 93, California 688, Idaho C. 188 and Wyoming C. 80 provide for the proper labeling, handling and sale of imported meats, eggs, poultry, and butter. The sale of such goods is to be indicated by the display of a sign in their place of business.

Mental Hygiene.—Hawaii Act 140 has established a psychological and psychopathic clinic which shall undertake to investigate the nature, causes, treatment and consequences of mental disease and defect within Hawaii. It is established with the power of management and control vested in the board of regents of the

University of Hawaii, the Board to employ competent persons to have charge of the clinic, conduct investigations, publish results, and give lectures and instruction pertaining to mental disease and defect with the approval of the Board of Regents.

Midwives.—Delaware C. 43 authorizes the state board of health to employ a nurse to educate and supervise the midwives of the state.

Milk.—Delaware C. 36 to prevent fraud and deception in the weighing and testing, buying and selling of milk and cream, provides for the examination and appointment of certified testers and the issuing of licenses and the making of tests. Iowa H. file 361 authorizes cities and towns to license and regulate milk dealers and establish standards for milk and cream. Massachusetts C. 45 requires the marking and sealing of cans and containers used in the wholesale distribution of milk or cream. Ohio H. B. 146 amends a previous law relating to the sale of pure milk, skimmed milk and standardized milk. Rhode Island C. 2070 establishes a new milk standard giving cities and towns the power to regulate the sanitation of milk. Wisconsin C. 409 fixes standards for the prevention of fraud in the sale of milk and C. 467 defines and fixes standards for condensed, evaporated, concentrated, sweetened condensed, sweetened evaporated, and sweetened concentrated milk.

Nurses and Nursing.—Arizona C. 70, Indiana C. 182, Kansas C. 267, Missouri S. B. 380 and Utah C. 130 altered the provisions governing the registration of graduate nurses. Indiana and Missouri specify the qualifications for licensed attendants, and Utah gives to the Department of Registration the power to appoint an inspector of hospitals and training schools for nurses.

Occupations.—Utah C. 130 has created a department of registration with power to exercise the duties of the state board of barbers' examiners, the dental examiners, medical examiners, nurses, optometry, pharmacy, and others. This department conducts hearings, examinations, etc., and issues certificates and licenses. Washington C. 67 in its administrative code has specified a director of licenses to perform all the duties vested in the barbers' examining board, the State Board of Chiropractic Examiners, the State Optometric Board, the Board of Osteopathic Examiners, the State Board of Pharmacy, and others. Wisconsin requires all public health nurses and public health instructors to register with

and be certified for employment by the State Board of Health.

Optometry.—Connecticut C. 276, Florida C. 8580, Missouri S. B. 333 and Utah C. 86 regulate the practice of optometry requiring the issue of licenses and specifying qualifications.

Osteopathy.—Florida amending C. 5946 of 1909, Hawaii Act 14, Oklahoma C. 30 and Washington C. 82, authorize the practice of osteopathy after the securing of a license. Hawaii and Oklahoma create boards of examiners specifying the qualifications to be demanded. Washington amends a previous law concerning the reciprocity and revocation of licenses and requires further that no license is to issue to any person who has failed in examination without re-examination.

Physical Education.—Connecticut C. 399 provides for health instruction and physical education in the public schools. Massachusetts C. 360 makes similar provision.

Pillow Industry.—California C. 92 regulates the making, remaking and sale of pillows, requiring that materials used therein shall be accurately described and presenting the manner in which they shall be labeled.

Public Comfort Stations.—Illinois P. 445 amended its law relating to wash rooms in certain employments requiring that they shall be so arranged that employees may change their clothes therein, shall be sufficient for the number of persons employed, and shall be equipped with lockers, hangers, hot and cold water, etc. Minnesota C. 294 requires villages and cities of the fourth class to provide public comfort stations with toilet and lavatory facilities near the business center. Rest rooms are to be free and to be kept in a neat and sanitary condition with suitable toilet facilities for women and children. These rest rooms may be in hotels or public buildings. Wisconsin has extended the public comfort station act to give governmental units the option to provide comfort station and rest room facilities in camp sites and other places of public assemblage. Five thousand dollars was appropriated for their supervision.

Public Health.—Illinois has provided for approximately twenty-five state health officers to be known as district health superintendents. Texas passed five bills relating to public health of which not one carried an appropriation for enforcement. Utah C. 58 requires the Secretary of the State Board of Health and his deputy or deputies to inspect during business hours (a) office equipment, tools,

instruments, laboratories, linen, and supplies of all medical practitioners, dentists, barber shops and barber schools; (b) all pharmacies, dispensaries, stores and places where drugs, medicines or poisons are compounded, dispensed or retailed.

Inspectors are to have free access to such places and to report in writing to the Director of the department of registration on such inspection, a copy to be sent to such person responsible for the condition and on refusal to put premises in a clean condition the license may be revoked.

The State Board of Health has power to adopt reasonable rules and regulations prescribing the sanitary requirements of medical practitioners, dentists, barber shops and barber schools, copies thereof to be printed and sent to each registered medical practitioner, dentist, and proprietor or manager of a barber shop or barber school.

Vermont C. 100 authorizes towns and incorporated villages to appropriate money for a resident physician or nurse.

Public Health Nurses.—Michigan authorizes the employment and compensation of public health nurses by townships. New York C. 130 empowers the board of supervisors in counties not having a tuberculosis hospital, to appoint and employ such public health nurses as the board may deem proper, and by C. 263 they may organize and operate clinics for the medical examination of persons who are or may be suffering from tuberculosis.

Recreation.—Ohio S. B. 81 enables cities, villages, or counties to acquire, maintain and operate playgrounds, play fields, gymnasiums, public baths, swimming pools, and indoor recreation centers and authorizes school districts to join in the maintenance and operation of such activities. Utah C. 57 regulates the cleanliness of swimming pools and provides for their licensing and inspection.

Restaurants.—North Carolina C. 186 providing for the inspection and conduct of hotels and restaurants has been reviewed. Iowa C. 199 provides that every building or structure kept, used, advertised or held out to the public to be a restaurant, cafe, cafeteria, dining hall, lunch counter lunch wagon, or place where food is served for pay to the public, except those used not more than one day in any week by churches, fraternal societies and civic organizations is termed a "restaurant" within the meaning of the Act. Before January 1 of each year application for

license is to be made to the Inspector of Hotels. Blanks, information required, etc. Every restaurant except those temporary in location and character, situated in a town having a system of sewerage shall be thoroughly drained, constructed and ventilated according to approved sanitary principles, to be kept and maintained in a clean and sanitary condition, free from odors, etc.

Utensils and places where food is kept or prepared is to be kept and maintained in a sanitary condition, and the use of soiled or insanitary tableclothes, napkins, or other tableware is prohibited.

Safety Devices and Measures.—Massachusetts C. 50 has amended its previous laws concerning hoods, hoppers, and suction devices on emery wheels for the reception of dust. These devices and connections are to be suitable and efficacious and approved by the department of labor.

Minnesota C. 113 requires employers to furnish helmets to employees engaged in any occupation or process of employment in which there is danger of serious injury to the eyes. The employees must wear such helmets and the design and material of the helmets is to be approved by the Commissioner of Labor.

Sexual Diseases.—Hawaii C. 200 established a venereal clinic in Honolulu under the direction and control of the territorial board of health and which is to be free to all residents of Honolulu.

Idaho C. 200 requires the reporting of venereal disease by any physician or other person, superintendent or manager of a hospital, dispensary, charitable or penal institution to the State Department of Public Welfare. State, county, and municipal health officers or their authorized deputies "when in their judgment it is necessary to protect the public health" may make examinations or cause examinations to be made of persons reasonably expected to have the disease. Prisoners are to be treated and the Department of Public Welfare is to make rules and regulations.

Idaho C. 201, Nevada C. 221, Pennsylvania No. 23, Vermont C. 213 prohibit the advertisement of cures of venereal diseases and certain sexual disorders.

South Dakota C. 339 permits state, county, and municipal health officers or their deputies to require persons infected with venereal diseases to report to a reputable physician and to continue treatment. Sources of infection are to be investigated and persons in a communicable state to be quarantined.

In Indiana C. 38 the fact that a person has a venereal disease does not act as a bar to any benevolent, charitable, penal and reformatory institution maintained in whole or in part by state funds. It is the duty of the official or superintendent in charge of such institution to institute and provide proper treatment and to carry out such laboratory tests as might be necessary to determine the nature, course, duration, and results of such treatment. The services of the laboratory of hygiene of the State Board of Health shall be available without charge for such laboratory diagnosis and tests as may be necessary. The State Board of Health is to cooperate in every reasonable way to prevent and suppress venereal diseases.

Pennsylvania No. 150 authorizes the department of health to make rules and regulations with regard to the examination of inmates of penal institutions suspected of suffering from venereal disease, and Rhode Island C. 2081 enacted a general law for the prevention and treatment of venereal disease. Pennsylvania has designated the state hospital for the chronic insane as a hospital for people suffering from syphilis.

Sewage Disposal.—New Jersey C. 46 regulates the discharge of effluents from sewerage systems or works into a potable water supply.

Swimming Pools.—Utah C. 57 provides that the State Board of Health has supervision over the sanitation, healthfulness, cleanliness and safety of public swimming pools, bath houses, swimming and bathing places and all related appurtenances, and the board is empowered to make and enforce such rules and regulations pertaining thereto as it shall deem proper.

It is unlawful to construct same without permit from the board of health; application to be filed stating sources of water supply, disinfection, heating, safety, etc., and all other information required by the state board of health.

Tuberculosis.—New Hampshire C. 194 by joint resolution provides for and regulates the treatment of persons in the advanced stages of tuberculosis.

In North Carolina C. 178 by amending a previous law it is provided that the county commissioners of any county may erect and maintain county tuberculosis hospitals. Wyoming C. 169 establishes a state institution known as the "Wyoming Tuberculosis Sanatorium."

Water Pollution.—Connecticut C.

395 creates a commission to investigate the pollution of streams. Kansas S. B. 118 seeks to prevent the pollution of water by oil, salt water, or refuse escaping from well drilled for oil or gas, and Rhode Island C. 2090 to prevent the pollution of the rivers and harbors of Narragansett Bay.

Workmen's Compensation.—Arizona C. 103, Connecticut C. 306, Delaware C. 186, Illinois P. 444, Maine C. 222, Massachusetts C. 310, Minnesota C. 82, Missouri H. B. 73, Nevada C. 161 and 218, New York C. 121 and 539, Ohio H. B. 47 and 378, Oregon C. 311, Pennsylvania No. 67, Rhode Island 2095, South Dakota C. 419 and 420, Utah C. 67, Washington C. 182, and Wisconsin C. 414, have extended or altered the provisions of the workmen's compensation acts. Arizona created a commission, altered schedules, etc. Illinois and Ohio specify that disability from occupational disease is to be treated as within the Workmen's Compensation Act. In Massachusetts reports of medical examinations under the compensation laws are to be filed with the Department of Industrial Accidents. Minnesota has recodified the law as has Missouri, the latter subject to approval by the people, November, 1922. Nevada C. 218 includes voluntary firemen in the Act. Oregon changed the schedule of ratings. South Dakota increases the rate to widows and children, C. 419, and makes it possible for a widow with children to secure the compensation allowed without waiting for the appointment of an administrator. Utah makes certain changes in the schedule and general scope of the law and provides, as does Missouri, that the obstruction of treatment or the unreasonable refusal of operation may work forfeiture of compensation. Washington has made the law applicable to public contract work (state, county or municipal corporations) engaged in extra hazardous work. The ratings and scope are changed also.

Bureau of State Welfare Organized

Dr. John M. Baldy, state commissioner of welfare, Pennsylvania, announced that the new welfare department would be organized with four different bureaus to look after different phases of state charitable work and named the following as directors of three of the bureaus: Dr. Ellen C. Potter, now with the state department of health, will be director of the Bureau of Children;

Bromley Wharton, who was secretary of the State Charity Board, will be director of the Bureau of Assistance, which will look after the state's charitable and benevolent work in hospitals and institutions; and E. J. Lafferty, member of the State Prison Labor Commission, will be Director of Rehabilitation, which will deal with rehabilitation work among the inmates of penal institutions. The director of the bureau of mental health, which is provided by legislative enactment in the measure creating the welfare department, has not been selected. The activities of the Bureau of Mental Health are to be devoted to perfecting and expanding the dual (state and county) system of caring for the insane, of expanding the activities of the state in the line of feeble-minded, and of starting an active and studied campaign of education with the object of leading to the future state care of these wards of the state. The Bureau of Children will have as its object not only standardization of all institutions caring for children, but shall aim to house as many children as possible in families rather than in institutions. The policy already has been adopted by the state in establishing the mothers' assistance fund.

Cancer in Germany

The statistics for the years 1914-1918 have recently been published and show that there has been no appreciable increase in recent years. In men the number has actually declined, from 23,494 in 1914 to 21,804 in 1918. In women there has been a slight increase, from 28,694 to 29,631. In 1904 the total average was 6.2 per 10,000, in 1913, 8.2. No regular laws can be deduced from these findings as in some districts the cancer mortality has advanced and in others declined during the years in question.

Directory of Child Health Agencies

A directory of child health agencies in the United States has recently been compiled and published in multi-graph form by the United States Children's Bureau. The directory lists the agencies according to states and furnishes information on the date of organization, the nature of the program, size of staff, name of executive, and form of support. It is planned to print this directory in more permanent form as soon as the data have been verified.

Medical Representation in Legislative Matters

THE report in a recent issue of the *Boston Medical and Surgical Journal* of the work of the Joint Committee on State and National Legislation is an illuminative statement both as it emphasizes the need of leadership in civic matters on the part of medical men and as it brings out the wide range of interests in which this leadership is called for.

Authority is generally conceded to professional opinion in technical matters and on issues of more or less minor importance pertaining to foods and beverages, the control of narcotics and poisons, or on moot questions relating to disease; but a surprising and inexplicable opposition to expert guidance is often encountered in legislative and popular opinion on such scientific issues as vaccination, for instance, or physical education, or maternity aid. The wide variation of opinion on matters of this kind which, if formed rationally, must be considered on basis of fact, not prejudice, brings out the increasing need of popular education on health matters as well as the necessity for the active participation of the medical profession in the formative processes of public opinion.

It must be admitted that in the past not only has the profession as a class stood somewhat apart, but it has never clearly and consistently stated its own case. Science has, therefore, become effective more or less indirectly and this

is to be considered in accounting for both the emphases and the gaps in health legislation.

That the public is not disinterested in medical and health matters is sufficiently proved by even the most cursory survey of recent health legislation, a summary of which is presented on another page of this issue. The first impression gained from a reading of this article is the wide range of matters covered by health legislation, and the large number of states and territories which are concerning themselves with measures looking toward health conservation. A general interest is manifested in licensing laws. Many of the newer laws have seen to it that wash rooms, with hot and cold water supply, are available in all industrial plants. Food laws are enacted with a precision of detail in regard to food factories, food handling, etc., that might seem to leave too little to the discretion of departments of health inspection. Georgia and North Carolina, particularly, have given marked attention to food laws.

We have in these acts another instance of adequate health ruling without the necessary provision for making it effectual in the legislation of Texas with no appropriation to carry it out. The whole accomplishment, however, is encouraging, for we see appropriations for health increased when the general tendency is in the opposite direction; we see simplification and coordinations replacing the cumbersome machinery of the past. We have a right, then, confidently to expect a higher order of efficiency and of productivity, general throughout the country and cumulative in its constructive work.

Winning the Business Man to Health Activities

WHEN officials seek public approval for deeds accomplished, they go to the business man; when politicians plan a coup of any significance, they consult the business man; when people are called on to vote bonds for needed improvements, they follow the business man. If public health work is to be impressed on the community's conscience, to become a live and functioning part and parcel of our daily lives, why not sell it to the business man? If we expect the Federal Congress, state legislatures, and local governing boards to grant questions of public health the same consideration now given to matters of less import to the common weal, we must win over the business man.

This is an industrial era. Industry can make war and end it. It can decide the fate of nations and people. Similar influence of business can be felt down to the lowliest community. Such a condition need not be considered a handicap to public

health advancement. Our mode of attack needs to be changed so that the present liability can be converted into an asset.

Business men are practical and expect adequate returns on any investment. If the health officer can demonstrate,—not only to his board or council—but to the business man, that by adopting certain measures, definite saving of lives and dollars have resulted, that better health of employees means greater efficiency in the plant and consequent increased profits, that better health of the citizenship means less poverty, and more money for the purchase of necessities and luxuries, that good municipal sanitary conveniences invite high class residents and new capital, then that same acumen and genius of business organization will be found in the support of the public health campaign. Health officers have been addressing themselves to a small select group and then wonder when popular support was not forthcoming.

Organized business leadership in the form of Rotary Clubs and Chambers of Commerce are beginning to evidence keen interest in the health movement. Rotary Health Week, observed in 1920 by Rotary Clubs throughout the United States by special health programs, will be repeated this December. Other clubs have shown similar interest and this should be encouraged. Insurance companies are taking an active part in the health campaign and private organizations of business men such as the Public Health Institute of Chicago, are leading the way in constructive public health work.

Business men should attend health conferences and every civic and business organization should be officially represented so they can become informed of the latest advances in the health campaign. Likewise health workers should aim to attend business gatherings to carry their message to business leaders. Public health work will be better supported morally and financially whenever the business interests are educated to its usefulness and won over in that way.

Health Correlates with Habits of Thrift

MORE and more as data are collected and correlated it is coming to be understood that health matters are inextricably bound up with questions of economics. Nora Milnes¹ in her very able analysis of "Child Welfare" declares that this branch should be regarded as one of the studies of applied economics, which may well be conceded if economics be defined as the study of mankind in the ordinary business of life. It has lately been deduced from figures ob-

tained in connection with safety work that the man of thrift is much less prone to accident than the man of the more unstable economic status. Thrift promotion is often a prominent feature of welfare work. Even insurance companies in reinstating lapsed life insurance policies are inclined to deal more liberally in the consideration of the physical conditions of applicants, but to scrutinize more closely their personal habits and business standing.

While many questions enter into what may be considered to establish the insurability of life, good habits and a normal range of interests and activities supplement the value of stability in health and conversely, life expectancy.

Insurance companies are discussing pro and con recent bank insurance plans which confer the benefits of life insurance in conjunction with savings accounts. Many companies, instead of regarding this as an infringement of their own sacred prerogatives, seem inclined to regard all service as valuable, and to accept as of mutual advantage any measure that involves the education of the public to the life insurance idea, and to habits of thrift. The public mind cannot fail to be impressed with the growing insistence on the part of many banks on life insurance being carried where extensive credit is desired.

Meanwhile, the insurance companies themselves are aroused to put their investigations on a more scientific basis. Prior to the entrance of insurance investigators into the field of actuarial and mortality studies, practically the only available statistics of any extent were to be obtained only through charitable and public institutions, thus necessarily representing so selected a class economically as not to be applicable for wide generalization. The figures of the census are so general in classification as to require a refinement of analysis seldom possible to the average research worker or permitted by the usually limited budget allowed for such study.

The records of life insurance companies have afforded much more precise information. Their availability and the breadth of their service will be greatly extended if success attends the plans formulated recently in Chicago by the Association of Life Agency Officers to establish a Central Bureau of Research at Carnegie Institute. It is significant that the more successful insurance companies have been the most liberal in the budgets made available for research, and it is expected that this advantage will be disseminated by the use of a central bureau of research. The advantage to the general public of work of this kind on the part of insurance companies is that it immediately becomes effective throughout the country. The health idea and health interests are

¹ L. E. P. Dutton & Co., New York, 1921.

immediately and permanently stimulated by it. Every means of stimulating research, therefore, or that serves to put it on a more scientific footing, is to be welcomed.

The Semi-Centennial of the American Public Health Association

THE SEMI-CENTENNIAL Meeting of the American Public Health Association held in New York City, November 14-18, was perhaps the most notable occasion in the history of the public health movement in America. The central figure of the celebration was Dr. Stephen Smith, the founder and first president of the association, a pioneer in the introduction of Lister's method of antiseptic surgery into America, and an associate of Dr. Elisha Harris in the sanitary survey of New York City which led to the enactment in 1866 of the first effective public health legislation upon this continent. In his ninety-ninth year, Dr. Smith attended the banquet of the Association and in a clear and vigorous voice read an address in which his youthfulness of spirit was evidenced by the fact that he used the achievements of the past century merely as an argument in favor of attaining even more notable progress in the fifty years that are to come.

The meeting was made memorable by the preparation of a jubilee historical volume entitled "A Half Century of Public Health," in which various authors described the progress made along public health lines during the past fifty years, and by an extensive health exhibit in the Grand Central Palace and a Health Institute under the auspices of the American Public Health Association, the United States Public Health Service, and other bodies, which is the first of a series of nineteen institutes to be held at different points throughout the country during the coming months. The registered attendance of more than one thousand members was representative of the entire country and the programs, particularly those of the public health administration, laboratory, food and drugs, vital statistics, and sanitary engineering sections, and the special sessions dealing with health education and publicity were of the highest quality. The New York meeting testified once more to the fact that this organization, representing as it does all that is best in the field of public health, is a mighty force for professional coordination and for public enlightenment. The election of Dr. A. J. McLaughlin of the United States Public Health Service as president for the coming year and the selection of the city of Cleveland as the meeting place for 1922 are both happy auguries for the immediate future.

Cooperative Rural Health Work of the Public Health Service

ACCORDING to information compiled by the United States Public Health Service less than 6 per cent of our rural counties are provided with local health service headed by whole time health officers. Rural health work, because of distances to be covered and relative greater expense, has not experienced the same progress found in urban health work, and cannot be expected to exhibit equal advancement unless it has the assistance and stimulation from state and Federal agencies.

The cooperative rural health work of the United States Public Health Service, though of recent development, has already demonstrated the wisdom and efficiency of such joint agreements, as appraised in *Public Health Reports*, by L. L. Lumsden. During the past fiscal year cooperative projects were carried out in 38 counties in 15 states. The total expenditure for health work in these counties was \$292,063.59 of which \$31,460.82 was furnished by the United States Public Health Service, the remainder coming from state and local governmental services and private health agencies.

The sanitary district formed by ten Cape Cod towns in Massachusetts, the special demonstration work in ten Virginia counties, the tri-state sanitary district with headquarters at Joplin, Missouri, are examples of cooperative agreements which have resulted in increased health appropriation from local governmental agencies and enlargement of scope of the local health program.

The policy of according Federal aid to rural counties in setting up adequate health machinery is fundamentally sound, as gradually the entire expense will be borne locally. The International Health Board has initiated several valuable health demonstrations on this basis. The Sheppard-Towner bill though shorn of many of its more valuable features by various amendments, likewise grants Federal support in the encouragement and stimulation of state and local health programs. Rural health work must receive direction and assistance from central agencies such as the state and Federal Government, if it is to take advantage of the many advances in modern sanitary science.

The Psychology of Golf

EVERY game from poker to chuckaloo has its element of psychology, otherwise it would not be a game. The competition, the concentration, the judgment, the self control, and the coordination between mind and muscle which

are required successfully to engage in any sport, bring out better than anything else the true character and mental makeup of the individual. The player is so busy trying to focus himself on the play of the moment that he is for the time being psychologically naked, and the other contestants, if they are not too self-absorbed, may, with ease, observe traits which on other occasions are carefully hidden from the world. This explains why so many friendships have been wrecked at the tennis court or the card table and, conversely, why what has hitherto been merely a pleasant acquaintance has ripened into a lasting respect and affection on the putting green. Also, it interprets many of the queer game groupings of individuals of apparently widely diverse personal characteristics. Many of the odd twosomes and foursomes seen on the golf course are merely the agglutination of complementary personalities, the golf addicts recognizing in one another certain elements of compatibility which to outsiders are cryptic.

It should be recognized that in a certain sense all games are abnormal in that they are attempts to deviate the subconscious. Thus, the man who is constantly repressing a desire to beat a frivolous wife, sublimates this baser urge into a two hundred drive, while the timid soul who apprehensively shrinks before a pompous head waiter, berates his caddy with the bravado of a buccaneer. The observance and analysis of golf players gives a fairly accurate judgment of what they truly are at base. Many a man who is a model of deportment in business and at home will indulge in soul-deep profanity at a wayward putt and many a player of scrupulous business integrity will "forget" a stroke at a critical moment. The man who is essentially mean will reveal his pettiness, the rash will disclose his temerity, the selfish will disclose his egocentric affection, the careful will demonstrate his caution, the liar will show his untruthfulness, and the patient his tenacity in the face of adversity. This unmasking progresses as the game proceeds, fatigue gradually lowering the curtain of self-concealment and a topped ball which on the first or second tee would have produced merely a temporary annoyance, will cause a torrent of rage on the seventeenth.

This brings into play the ability for sustained effort. In golf, as in life, many a man does brilliantly at first, only to go all to pieces later. Similarly, men have their ups and downs, playing or working with success or failure for a time, only to reverse this form, subsequently. In both there is an extraneous element at bottom. One cannot simultaneously worry about business and golf. To succeed at either, the matter immediately in hand must receive undivided attention. This is

why the man with a grasshopper mind, which leaps spasmodically from point to point, cannot win. Also this is the reason that golf is a relief, a relaxation, a soul balm when entered into wholeheartedly, with concentration on hitting the ball.

And here enters the psychology of the difference between theory and practice. The essential thing in golf is to hit the ball, to hit it squarely with a clean stroke and the force requisite to carry it to destination. The practical man realizes this and acts accordingly. The theorist sprays his mind about, on the weight and composition of the ball, the whippiness of the shaft, the position of his feet, the cut of his breeches, the droop of his shoulders, and the flexibility of his wrists. His caddy groans under a sack of unused clubs, the player fritters away his money and his energy on an unsuccessful game and his irritability increases in the inverse ratio to his failure until he becomes the pest of the course. On the other hand, the practical player neither clutters his mind nor his golf bag with useless things. He concentrates on a half dozen well tried clubs and hitting the ball. He does not shy at hazards, nor blame his caddy, the weather, nor the turf for poor strokes. He realizes that both success and failure are impostors and he plays golf as a game, not as an intense matter of life and death.

In all of this the element of faith plays an important rôle, faith in one's self without over self-confidence, faith in a particular club to do a certain thing, and faith in one's caddy. Not infrequently a lost ball is disastrous because the player subconsciously remembers that the caddy has just lost a ball for him and he raises his head lest the caddy in whom he has lost faith will lose another. The attitude on the tee speaks volumes about the player's self-confidence. The futile foot-shiftings, and flourishes, the squatting and shoulder wiggles, the careful preparations interrupted to readjust the hat or lower the tee, the frequent peerings at the distant flag, these all tell of indecision and uncertainty. Up to a certain point they are readily cured by the simple psycho-therapeutic measure of telling the player how many different kinds of fool he is making of himself and why. Then he will understand why the good player is able to walk right up to the ball and smite it on the nose. Certainly if one-armed, one-eyed, and variously crippled men can overcome their physical handicaps, normal individuals can rise triumphant over self-imposed mental obstacles.

Just as some men become drunkards with their first bottle of beer so do some become golf habitués at the first tee. They are the hopelessly incurable to whom golf is the all absorbing passion, par the rule of life and the fairway a holy

temple. They are like the psychiatrist to whom heaven was a perfect golf course with a dementia praecox patient for an opponent.

Poor, deluded mortals, these golfers, revealing their hidden personalities with every stroke. The braggart cannot hide his weakness, the dishonest his crookedness, the miser his sordidness, nor the real man the greatness of his heart, once they are out on the springy turf struggling with a perverse bit of rubber which, like the soul of man, begins life a resilient thing of purity and at the end of the game is discarded, hacked, marred and soiled, though subjected to many repaintings. Pitiful indeed are their strivings after unattainable perfection, for though they labor all their days yet will the end still find them unsatisfied, for none can equal the Great Inventor of it all. Yet through the imitation of perfection, comes peace of mind, health of body and length of days, for the psychology of golf is the picture of life's self.

Dr. Harvey Cushing, President-Elect American College of Surgeons

AT THE recent meeting of the American College of Surgeons Dr. Harvey Cushing was named as President-Elect. Dr. Cushing was born in Cleveland, O., April 8, 1869. He received the degree of A.B. from Yale in 1891 and the degree of A.M. and M.D. from Harvard in 1895. He served as house pupil in the Massachusetts General Hospital and, after some years abroad, on the staff of Johns Hopkins Hospital, where he remained over a period of fifteen years, during which time he was perfecting himself in his specialty of brain and nerve surgery in which field he stands pre-eminent. He is professor of surgery at the Harvard Medical School and surgeon in chief at the Peter Bent Brigham Hospital. It is expected that his method and training will enable him to render outstanding service in his new capacity.

Joint Functional Group on Statistics

INTEREST attaches to the recent organization of an interstaff committee of the National Health Council, known as the Joint Functional Group on Statistics, the primary participants in this Committee being the three organizations of the National Health Council which employ full time statisticians. The personnel of the group is at present made up of: Edith M. Furbush of the National Committee for Mental Hygiene; Miss Mary C. Clark of the American Social Hygiene Association; and Jessamine S. Whitney, secretary of the National Tuberculosis Association. Dr. Louis I. Dublin will serve as advisory

member of the Committee, and Dr. Donald B. Armstrong of the Common Service Committee and National Health Council will act as chairman. It is the creditable design of this Committee to organize the consideration of statistical problems, to make available all data on a given subject prior to undertaking new work, and to make possible more comprehensive studies by means of cooperative research.

THE fifteen hundred or so physicians throughout the country who are making a specialty of industrial medicine, either in independent practice or in professional activities more or less closely associated with the special problems in a given industry, are being addressed severally and collectively by members of the American Association of Industrial Physicians and Surgeons in the membership campaign.

There are many reasons why every reputable physician who is devoting all or part of his time to industrial medical practice should identify himself with the Association. The necessity for keeping knowledge up-to-date is served by organization. Disorganization means defeat; while correlated research and calculated team work makes for increasingly higher standards. Distrust of specialization is born of situations in which the professional man sacrifices perspective to over-individualization. The Association meetings and the columns of THE NATION'S HEALTH are an open forum for the exchange of ideas. The Association will without doubt receive new impetus from the acquisition of new members and will arrive at a wider effectiveness through a re-statement of its purposes and the dynamic urge born of aggressive team work.

OBSERVANCE of Health Week during December 4 to 10 by Rotary Clubs throughout the country has been set by the International Association of Rotary Clubs. Rotary Health Week was observed for the first time in 1920, and in many states considerable interest in public health was manifested by the business and civic leaders. The period set aside by Rotary Clubs corresponds with the Tuberculosis Week of the National Tuberculosis Association and its affiliated organization, so that plans for the health week are frequently prepared under the direction of both agencies.

THE *West Virginia Healthfinder* is the name of a new health monthly which made its first appearance in October. The *Healthfinder* is published by the West Virginia Tuberculosis Association and its first issue contains illustrated articles of the state sanatoriums.

Legal Requirements Regarding Seats in Industry*

Theory and Practice are Nowhere More at
Variance Than in Posture Requirements

BY EDITH HILLES, BUREAU OF WOMEN IN INDUSTRY, NEW YORK STATE INDUSTRIAL COMMISSION, NEW YORK CITY

LEGISLATION develops so slowly that it is almost always far behind the most progressive thought in the community, and the laws regarding the provision of seats in industry are no exception. Practically all these laws, both in this and foreign countries,¹ are very general in wording, and except in a few instances the requirements are "suggested" rather than strictly enforced with prosecutions. In most instances the "provision of seats" is the only thing which has been required by law, and no distinction is made between a box, a barrel, a round top stool, or the best physiologically constructed chair.

Laws in Foreign Countries

It is something of a revelation, however, to see the number of countries which have requirements of one sort or another on their statute books for the provision of seats in work places. Most of the laws which exist require seats for women or for minors, although in Germany and Austria the law reads "adequate" or "sufficient" seating accommodations, without a sex limitation, and the Australian Factories and Shops Act (Victoria), clearly demands "compulsory

provision of one seat for every three persons, irrespective of sex, employed in shops." In Switzerland (Ticino), the law also states "whenever possible sitting accommodations shall be provided for male and female employees in warehouses and shops."

France has a general provision for "one seat for each woman shop assistant," and certain of the French colonies are more explicit; for instance, in Tunis: "Stores, shops and other places connected therewith, in which merchandise and various objects are dealt with or offered to the public by women employees, shall be provided in each room with seats equal in number to that of the women employed there." The Australian law in New South Wales, Queensland, Tasmania, and western Australia, and the laws in Belgium, Spain, New Zealand, Peru, Argentina, and The Netherlands, include women or women and minors only; the number of seats is either required to be "adequate" or "one to three," or "one for every woman."

Greece has a special royal decree in regard to hygienic conditions and safety of workers in factories and work shops, passed in 1913, which demands that "in factories or work rooms where tobacco is prepared or manufactured, the employer must provide seats at least half a meter high for the workers." The only other law in Greece regarding seats provides for seats for women and minors "enough for occasional rest

in retail sales places and in book-keeping offices."

The Home Office of the Ministry of Labor for the United Kingdom has taken particular interest in the problem of industrial seating, and has recently printed a welfare pamphlet on this matter.² The Shop Act of the United Kingdom (1912), provides for "compulsory provision of one seat for every three women assistants employed in serving customers." This provision was originally made in 1899 as a separate Act; in 1916 the Factories Act of the United Kingdom empowered the Home Secretary "to make order for any factory or workshop or class of factories or workshops requiring the provision of seats in work rooms." This is one of the "Welfare orders" made in the Act. Up to October, 1920, four orders had been made: one for munition plants, one for oil cake mills, one for a type of cannery, and one for laundries. In Norway, Denmark and Sweden there are no specific regulations for the provision of seats, but the factory inspectors "make suggestions to employers." A law was prepared and introduced in Denmark for the provision of seats "in commerce," but was not passed. The Secretary for the International Association for Labor Legislation in Christiania, writes that "We consider it to be a deficiency in our factory law that it

*The data in these articles are taken from the report of the Bureau of Women in Industry of the New York State Industrial Commission, on industrial posture and seating. The illustrations used are from those courteously furnished the Bureau for their report.

1. Material on the laws of foreign countries was secured for the Bureau by Dr. Royal Meeker of the International Labour Office of the League of Nations, and also by the secretaries of the International Association for Labor Legislation in four different countries.

2. Seats for Workers in Factories and Workshops: Welfare Pamphlet No. 6, London, Govt., 1920, 16 pp.

How one company utilizes its rest periods to promote good posture

does not have any provision regarding seating, and I am pleased to tell you that the appointed commission for the improvement of our factory law, pays attention to this drawback in our legislation and is going to propose that proper seats shall be provided for all workers (both men and women), whenever it possibly is consistent with the kind of work."

United States Laws

The laws in our own country have followed the same general trend; with the exception of a few laws requiring seats for street car motormen and conductors, provisions exist only for women. Salesgirls were the first group of women for whom seats were provided by law, because of the early recognition of the danger of constant standing, and New York State passed a law containing provisions for them as early as 1881.

By 1920 forty-seven states had laws requiring seats in mercantile establishments, and thirty-six states required seats in both mercantile and manufacturing establishments. A few states require seats for women in practically all work places.

Lack of uniformity in legislation makes these provisions very confusing, and in many instances the wording is so loose that enforcement is not only difficult but the meaning of the law itself is not clear.

The laws as they stand offer comparatively little protection to health, because even when a sufficient number of seats is provided, it is practically impossible to see that employees are allowed to use them.

Employees shall be "permitted to use the seats," when such use will "not interfere with the discharge of

duties," or when "not engaged in the active duties in which they are employed," or "for the reasonable preservation of their health." Some laws attempt to reinforce this loose wording by saying that no "arbitrary rules, regulations or orders shall be made preventing the use of such stools or seats," but too often an understanding exists that if a girl is found sitting down she is liable to discharge. In some work places the old idea still holds,—that to be seated is to be lazy.

Though the difficulty of determining when seats can be used is not to be denied, it is true that in many

cases a slight change in the work place would make seating possible where before it had been considered impossible.

The number of seats to be provided is in most cases designated as "suitable," though in a few states a proportion of at least one seat to every three employed women is required.

The type of seat to be provided is usually left to the "discretion" of the Industrial Commission or the inspectors. Three states, Minnesota, Ohio, and New York provide that where "practicable" seats with backs shall be provided. A few states supplement the laws by orders of a more specific character. Kansas, for instance, has an order requiring that "all seats shall have backs and foot rests, broad and firm enough to be convenient while working."

The most specific orders of any state are those of the Industrial Welfare Commission of California,³ made for women employed in canneries in that state. This order was based on the most careful study which has yet been made for a particular industry. The order reads:

As far as and to whatever extent, in the judgment of the commission, the nature of the work permits, the following provisions shall be effective: seats shall be provided, at work tables or machines for each and every woman or minor employed, and such seats shall be capable of such adjustment

3. California Industrial Welfare Commission, Bulletin No. 2-a: The Seating of Women and Minors in the Fruit and Vegetable Canning Industry of California. Harold Mestre, Sacramento, Govt., 1919, p. 3.

The position of this worker is conducive to fatigue and productive of the general symptom-complex known as "abdominal crease symptoms." Courtesy The American Posture League.

and shall be kept so adjusted to the work tables for machines that the position of the worker relative to the work shall be substantially the same whether seated or standing. Work tables, including cutting and canning tables and sorting belts, shall be of such dimensions and design that there are no physical impediments to efficient work in either a sitting or standing position, and individually adjustable foot rests shall be provided. New installations to be approved by the commission.

Enforcement a Problem

The enforcement of laws requiring seats in industrial establishments, is, of course, the chief problem. A requirement on the statute books means nothing if no action is taken to carry it out. The Pennsylvania law, for instance, requires that "at least one seat shall be provided for every three females employed or permitted to work, and all seats shall, during work hours, be conveniently accessible to the workers for whose use they shall be provided," yet in a study of mill conditions in the Philadelphia textile industry, made in 1918 and 1919, by the National Consumers League under the authorization of the Secretary of War, it was found that in spite of the requirement for seats for women in the mills—"Of the forty-eight plants in which this matter was carefully noted, twenty-nine provided no seats at all; in sixteen others women used boxes and bales, or occasionally a few stools scattered about. Six had properly obeyed the law, but these, with one exception, were small plants employing less than twenty-five women."

These laws seem very far behind indeed when the experiments of some of the most forward looking factories and mercantile establishments are viewed, where industrial engineers have really attempted to "fit the work place to the worker." Campaigns for "seats for salesgirls," and rapidly developing interest in the study of fatigue, have brought the question of seating to the fore. The reports of various committees studying fatigue, of the British Health of Munitions Workers' Committee, and the Federal as well as State Labor Departments, and of an infinite number of non-official groups dealing with industry, have all emphasized the importance of posture and seating at work. Their conclusions and recommendations are much alike in the standards suggested and, of course, go ahead of any legal requirements. Perhaps the best general summary of the points which they tend to bring out can be found in the Bulletin issued as a flier in an executive series of the National Safety Council, which reads as follows:

A seating atrocity encountered in the investigations of the Division of Women in Industry, New York Department of Labor.

The day of the ordinary wooden chair and of stools, without backs, as a part of modern factory equipment is past. Factory managers and the manufacturers of factory chairs know that a chair, to have utility, must be adjustable, so that it can be more nearly physiologically correct. During the last few years, the manufacturers of factory equipment have given some consideration to the things that make a factory chair desirable from the standpoint of physical comfort. Chairs should support the part of the body receiving the greatest strain from the work. The legs of the chair should be adjustable as to length, to suit the height of the user. A back rest which can be raised or lowered is generally desirable.

For certain operations the factory chair must be high. Under such conditions a suitable foot rest should be provided. In most cases the foot rest should preferably be attached to the work table, rather than to the chair. It should be large enough, and placed in such a way that the operative may be seated in a normal position.

When the work requires constant standing, chairs should be available for use during lulls in the day's work, and the employees should be encouraged to use them. Wherever possible, it is well to arrange the work so that the operator may stand part of the time and sit part of the time. Change of position appears to decrease fatigue and increase production.

The encouraging thing is not what has already been written into the existing laws and standards, but the fact that we have reached a time when shop equipment is recognized as needing study and needing standards, not only for the sake of economy and efficiency in production, but also for the sake of the workers who must be considered as human beings.

Science does create the will to serve.—Todd.

Engineers Plan to Confer on Industrial Waste

In a statement recently made public by the American Society of Mechanical Engineers, announcement is made of the five-day annual meeting to be held in New York City December 5 to 9, to consider the hearing of the investigation of industrial waste recently completed by the American Engineering Council of the Federated American Engineering Societies. Speakers from many cities participated in a program embracing a wide range of subjects of public, technical, and social import. Education was the theme of special sessions. At this meeting Dean Dexter S. Kimball of Cornell, the new president of the Society, and other officers were installed.

"The reconnaissance report on waste in industry is the result of five months of intensive study, carefully planned and rapidly executed," said Secretary Hoover. "A part of its value lies in the speed with which the work has been done and the promptness with which it presents definite lines of future action.

"It reveals facts which may serve as a foundation for an advance in American industry. It has a special message for government officials, financial, industrial, and commercial leaders, labor organizations, economists, engineers and research groups, the general public and the press."

There is an unmistakable trend in modern social reform toward collective control over all conditions of community life.—Todd.

Mobilizes for Membership Drive

The American Association of Industrial Physicians and Surgeons is now six years old and has five hundred fifteen members. Membership has been increasing steadily since the inception of the Organization.

It is conservatively estimated that there are at least two thousand five hundred physicians in the United States engaged in some form of industrial practice. Surely, one thousand of this number should be bound together in an organization whose purposes are (a) to foster the study and discussion of the problems peculiar to the practice of industrial medicine and surgery; (b) to develop methods adapted to the conservation of health among workers in the industries; (c) to promote a more general understanding of the purposes and results of the medical care of employees; and (d) to unite into one organization members of the medical profession specializing in industrial medicine and surgery for their mutual advancement in the practice of their profession.

If each one of our present five hundred fifteen members will activate himself sufficiently, he can secure at least one new member. We are counting on a genuine expression of cooperation from everyone. The officers and directors of the Association are earnestly striving to develop the organization to its fullest possibilities of usefulness and in the very nature of things, we can do more for the advancement of the Association if we have an increased membership.

No matter how small a part of your time is devoted to industrial practice, you are eligible to membership. Our dues are five dollars yearly, but to join now will cost only two and a half dollars. This will pay your dues to May 1, 1922. Membership entitles you to:

(1) Our official journal—THE NATION'S HEALTH—which contains full reports of all the affairs of the Association, together with other interesting articles on industrial medicine.

(2) Bi-monthly abstracts of current industrial medical literature.

(3) Reports and digests of interest to those engaged in industrial work.

(4) Privileges of the annual meeting which is to be held in St. Louis May 22-23, 1922, in conjunction with the meeting of the American Medical Association.

May we count on you who are al-

ready members to do your part in this campaign for one thousand members? Please do not fail us.

WM. ALFRED SAWYER, M.D.

AN ABSTRACT of industrial medical literature was sent to each member of the Association the middle of November. If you did not receive it, please advise the secretary. You are entitled to one and it is worth having. With this abstract was a mimeographed letter regarding the membership campaign which is now in full swing. With this letter was a bill for an assessment. This assessment is important and must be paid at the earliest possible moment. Look it up and attend to it.

The meetings of the Industrial Hygiene Section of the American Public Health Association, held in New York City, November 15 to 18, were well attended and full of interest.

Dr. C. H. Watson's paper on "The Physical Examination of Higher Executives" demonstrated very clearly the need and value of such periodic surveys of industries leaders. The executive is just as susceptible to the benefits of the physical examination as is the man in the ranks. Dr. Watson feels that much would be accomplished if, at the beginning of an executive's service he could be examined and advised as to his fitness for the task before him. Once the grind grips him, he quickly forgets necessary health measures and before he is aware of it, is on the road to a breakdown. However, in many cases the executive's physical ability is far above that of the rank and file, and he soon realizes the necessity for proper care of the physical machine.

Dr. Vermilyea of the Guarantee Trust Company called attention to the frequent lack of thought with which physicians in industries and commercial houses are chosen. Often they are selected because they happen to be the family physician of the president or some other officer. He stated that this procedure has frequently resulted in heart cases being cared for by a gynecologist, and patients with paresis being placed in the hands of a surgeon.

Mr. Edgar Sydenstricker of the United States Public Health Association, in his paper on "Morbidity Records in Industry," said that in most industries records of sickness were

kept in connection with sick benefit organizations and only absences extending over three to seven days were recorded. To arrive at a true estimate of sickness, figures must deal with sickness from the first day's absence. The short illness is often the symptom of ill health and indicates the time for preventive measures. He also urged that employment and sickness records should be correlated and we should determine just who are responsible for the absence. It is often found that from 15 to 20 per cent of the force are responsible for 60 to 70 per cent of the lost time.

Dr. H. W. Gentles of the American Red Cross and Dr. R. R. Sayres of the United States Bureau of Mines demonstrated the unquestionable value of prone pressure resuscitation over all the other forms. There has been a distinct tendency of late to use the various machines now on the market to the exclusion of the simpler, safer, and surer way provided by the Shaeffer or prone pressure method.

Dr. John R. Murlin of the University of Rochester presented a splendid paper on the "Workingman's Diet" and an effort will be made to get it before the members in its entirety.

Dr. E. L. Fisk, in his paper on "Fatigue," emphasized that little can be accomplished in the study and correction of fatigue until the numerous physical defects in workers are corrected. It is a problem in pathology as well as in physiology.

The paper on "Dental Work as a Prophylactic Measure in Improving the Physical Condition of Employees," given by Dr. Thaddeus P. Hyatt of the Metropolitan Life Insurance Company, and discussed by Dr. Henry S. Dunning of the College of Physicians and Surgeons, New York City, was most valuable. We may be able to have it published in our journal later. It will, of course, appear in the *Journal of the American Public Health Association*. He stated that the bacteria in a clean mouth are not harmful, but in the dirty mouth the virulent bacteria are present. He defined a clean mouth as one having no deposits, no inflammation, and no decay. He has found fatigue in every case of dental infection.

Already we are hearing from our members on the assessment levied in November. How about you? In the next issue we will be able to give a list of our members who are putting their shoulders to the wheel. Will you be one of them?

Life Saving Makes a Popular Appeal

Social Sense Demands Support of Management and of Engineering and Medical Departments

BY OTTO P. GEIER, M.D., CINCINNATI MILLING MACHINE COMPANY, CINCINNATI, O

THE industrial physicians' exhibit at the Cincinnati Health Exposition marked a step in civic progress. It served to emphasize the claim that the health and safety of any community is a measure of its prosperity, intelligence, and progress—that no community which neglects any means of imparting to its people the knowledge of the way to health has fulfilled the duty of government for which it is organized. It set forth the fact that the making of men is quite as important as the making of goods. It undertook to prove that intensive health work in industry is a practical paying proposition in increased energy and good will, and as such is a big factor in the industrial human equation between employer and employee. It sets forth the principle that good business is based on justice and right—that all men at heart are square and are moved by the same human emotions; that all men seek leadership, and that society fares well or ill, depending upon whether the leadership that appears is sane, intelligent, constructive, or whether it is irrational and destructive—that the employer is largely responsible for the prevailing type of leadership in our communities; that the right and wrong of our present industrialism so thoroughly permeate individual and collective thinking that we are right or wrong in our mass consciousness just in the degree in which industry succeeds or fails in establishing high principles of action and consequent deserved leadership.

World Statesmanship Needed

Good citizenship is needed today as never before. The world's turmoil can only be made orderly by clear thinking and highmindedness in public, business, and private life. America, drawn into the whirlpool of world policies, needs a high quality of statesmanship and this, in a democracy, can result only from a high type of citizenship, at peace with itself and seriously alive to every opportunity that will conduce to national and world welfare.

The day has passed when our countrymen can assume the fatuous complacency that we are self-sufficient—

that we are rich—independent of Europe's social and economic problems—safe against the types of class clashing that are undermining all the structures of the old order of things abroad. Let us beware of foolish vainglory. Struggle and service of a new type alone can save us from becoming engulfed more or less in the world's madness.

Upon the stability of our industrial system largely depends the stability of our international relations. We must be able to show that we know how to govern ourselves before we can help other nations mould their disrupted selves once more into secure governments. Democracy is on trial.

The far seeing industrial leader knows that we cannot secure the needed energy, cooperation, the willingness to produce, out of men whose bodies are cramped by sickness and whose minds are twisted and poisoned through a rankling sense of injustice or through unnecessary suffering by injury and ill health. The intelligent employing groups know that the new competition will not permit the wastage of millions weekly on account of preventable illness and accidents. This country could perhaps stand this loss when the products of its natural resources were finding ready markets the world over but not under present conditions.

Now we must stop the leaks—all the wastage, not only industrial but public and political. Big men are needed everywhere, to think, to plan for the people as a whole, to assume leadership, for then only may we hope that America may continue to hold its place and yet prove again the wisdom of our forefathers in founding this democracy. Are the industrialists meeting this challenge for leadership?

New Sense of Responsibility

That management here and there is taking serious account of its stewardship was indicated at a meeting held recently in Boston where the representatives of the Associated Industries of Massachusetts, the Boston Employment Managers' Association, met in conference with those of

the American Association of Industrial physicians.^{*} How these business men evaluated industrial medicine may best be shown by brief quotations. Mr. Andrews, the president of the Associated Industries, said: "The employer, not as a matter of charity—but as a matter of sound business methods and as a matter of discharging an obligation toward those who are associated with him, finds that there is something to be done by management in relation to health of his workers." Mr. John Spence, works manager, Norton Grinding Company, in concluding his appreciation of the value of medical supervision, said: "I am quite convinced, however, that even from the standpoint of a money valuation that there is just as much profit, if not more, in this kind of work as in the careful maintenance of the plant." Mr. S. A. Robertson, manager, Eastman Kodak Company, speaking to the same point and referring to their 120 per cent wage increase since 1914 with only 27 per cent increase in labor costs said: "What part of this increase in output the medical department is responsible for no one can tell, but we are convinced that a good ratio of that increased production is probably due to the care of the physical condition of the workman. . . . and unless he (the employer) is big enough to put these things over and get the cooperation of his employees he will be a failure in the manufacturing business." Mr. Howell Cheney of Cheney Brothers, South Manchester, Conn., speaking on the subject of Medical Service as affecting industrial relations, said: "To some degree the stability of these United States depends upon the effectiveness of your contribution of medicine to the industrial organization. It is impossible to doubt that the industrial physician has made a great contribution to this job of bringing about better relations between the employer and the employed; that should he go, industry will have lost what it never can replace in other ways. Having achieved that vision, the battle is half won."

^{*}See symposium of papers in September issue of THE NATION'S HEALTH.

The **Making of a Radical**

**UNSAFE,
UNCLEAN WORKING CONDITIONS,
FREQUENT ACCIDENTS,
UNNECESSARY ILLNESS,
WASTEFUL METHODS,
CARELESS TREATMENT OF EMPLOYEES,
DRIVING RATHER THAN LEADING,
SLIPSHOD WAGE SYSTEM.**

**All these things produce constant
dissatisfaction & Irritability
in the shop and at home.**

Unnecessary tensions, inflexible resistances, and lost motion mark the discontented workman.

Industrial physician and nurse, safety man and workman joined hands at the recent Cincinnati Health Exposition to demonstrate to the one hundred thousand or more visitors that medical supervision in industry is a vital factor in any health program, community or personal; that it is doing for the adult not only what medical supervision is doing for the school child, but that it is a great social and educational force for the employer, the employee, as well as engineering, medical, nursing, and dental professions.

To our knowledge, this was the first attempt on the part of the new specialty of industrial medicine to crystallize in the form of a public exhibit the purposes and possible accomplishments of health work in industry, and it is felt that a profound

Fatigue studies that concern themselves chiefly with the increase of efficiency through the elimination of unnecessary motions could be well supplemented by consideration of waste through unnecessary emotions. Unprotected machines, insanitary working conditions, undue noise, evoke needless tensions, hampering inhibitions, and even subconscious obsessions of fear that consume the workman, mar the product, and become the source of endless frictions.

impression was created thereby in the minds of those interested in social progress.

The Workman Speaks

Color and action were given to the exhibit in that machinery was in motion in the two contrasting miniature work shops, where machine operators, taken out of industry, held the attention of the visitors all through the afternoons and evenings by their constant comments on the advantages and disadvantages of their respective working conditions.

The man in the overalls held the stage not to decry working conditions, but constructively to criticize the good and the bad in present day methods of production and in simple language to point the way to safer and more healthful working conditions, with a larger output per man, with better wages, with less injury and sickness, with friendlier relations between employer and employee, with fewer burdens on society and with better citizenship throughout.

The shower of sparks off their respective emery wheels always drew a crowd to the rail in front of their little shops. Then each in turn would enliven their audiences with the feel-

ings that come to workmen as they face their daily jobs, explaining how these feelings are influenced by the conditions under which they work, how it affects their bodily and mental vigor, how it affects their output in the working hours, and finally, how it influences their behavior to their families and to the community after working hours.

Almost all of us feel ourselves elected to teach the workman better ways of living, but when Ed Grosbernd, the hard fisted, fearless eyed demonstrator in the bad shop, a veteran of the Spanish War, standing in his overalls before an audience of more than four thousand five hundred in the great Music Hall, was introduced for a few minutes' talk, he was warmly received. When in short, terse sentences, with the spirit of the Crusader, he drove home to that audience the fundamentals of health, safety, and sanitation and their effect on the workman's mind, followed with a plea directed to employers, employees and the public to get behind such efforts, the audience thundered its applause beyond that granted any of the great national health speakers of the exposition week. Ed's short, sharp jabs at the fundamental

Shop surroundings like this require no compromises on the part of the workman. Secure in satisfactory working conditions and treatment, unhampered by ambiguous impulses, he finds health and joy in his work, and efficiency marks the performance of his day's work.

truths was followed by a splendid address on "The Health of the Worker" by Dr. Woods Hutchinson. But that famous publicist gave expression later to a feeling that was in all of our minds that evening, and that is, that as propagandists we have not taken count of the psychology of the workman's mind and that there are many Ed Grosbernds in our factories who could assist us marvelously in our educational endeavors.

On this same platform sat also the safety worker, Lindley Moore, who was in charge of the good shop. He was introduced as one who had given Uncle Sam twelve years of service in the Navy and now is taking the training as a safety man under the Federal Board of Vocational Training, giving promise of becoming one of the best safety and sanitation teachers in industry. A snappy sailor salute was all the audience got from Lindley. The industrial nurse also was presented, and she, along with the industrial physician on the stage, was shown to be another link in that chain of workman, safety, and sanitation man, doctor, and nurse, from whom is expected so much to promote health and welfare. But to return to the industrial physicians' display in the main exhibit halls:

To begin with, it was a joint exhibit of the work of ten companies in this vicinity employing full-time physicians. Upon my able associate, Dr. C. L. Ferguson, fell the many weeks' task of gathering medical, surgical, dental, and employment data upon which were based the posters and graphic representations used in the exhibit. Lack of standardization of records in this field, like in all others, made the task of collecting the statistics difficult.

A Composite Picture

Our general plan was to give the public a composite view of industrial medicine as it is practised in the ten plants, presenting rather the average conditions rather than the advanced work done in any one or more of the plants. It was interesting, for instance, to note that 11,800 physical examinations were made in all in 1920; that the average percentage of rejection was 5.7 per cent; and that rejections varied from 1.2 per cent to 8 per cent. It was impressive to note that among 11,800 employed, 70,000 medical cases and 35,000 surgical cases visited eight industrial dispensaries, making a total of 250,000 visits and revisits for all causes.

Some of these industries reported

BETTER Citizenship

Safely guarded modern machinery.
Education in **SAFETY**.
Clean working conditions, adequate.
Ventilation and lighting.
Reasonable comforts and conveniences.
A fair wage system.
Considerate personal relations.

These factors induce team work,
fair play, good shop government
on all day long example of our
responsibilities to job
Self·Family·Citizenship.

The sharp contrast between the good and bad shop is reflected in the characteristics of the workmen.

that as high as 7 per cent of the working force daily sought the physician's aid for one reason or another. The average ratio of medical to surgical cases was as 7 is to 3.5. The collected data showed, on the other hand, that almost invariably the sickness rate and absence because of sickness was materially reduced, in some instances being cut in half; that lost time from infected wounds after installation of medical service, with its prompt and proper treatment, reduced infection cases to the negligible point. The effort to collect comparable statistics proved to the cooperating medical departments the necessity for standardizing their records and in the interest of determining what may reasonably be considered the irreducible minimum of record that will still furnish sufficient in-

KNOW THYSELF

10,000 physical examinations were made during 1920 by 6 plants, employing 11,000 workers.

A small % had contagious diseases; epilepsy, very defective vision, disease of the heart, lungs and kidneys, preventing employment.

Few of the 10,000 had ever been examined.

All were advised of physical impairments and referred for medical or surgical treatment.

Spread of tuberculosis & other contagious diseases in the plant were prevented.

formation for intelligent deductions as to monetary and other values of health work in industry.

It was useful, for instance, to contrast the fact that while eight industries furnished 11,800 men convenient clinical facilities for 250,000 visits in 1920, the out-patient department of the Cincinnati General Hospital, with its score or more of physicians and nurses, afforded but ten thousand patients clinical facilities for thirty thousand visits. Even with free medical service, the cost approximated twenty thousand dollars. This comparison becomes even more interesting to society when it is realized that preventive work and early diagnosis, before incapacity takes place, generally obtain in the case of the industrial clinic, thereby preserving these workers as independent units of society by maintaining their health and earning power and thus preventing their migration into the class of charity seeking individuals found at the public clinics and hospitals. Here one naturally raises the next question, and that is, what proportion of the nearly six hundred thousand dollars spent by the General Hospital on ten thousand patients as expense for 182,354 hospital days, might have

been saved if industrial medicine, which cuts down absence on account of illness one-half, had been more generally introduced in Cincinnati years ago. In other words, is society spending its money for medical and surgical aid at the point at which it will accomplish the most good?

In compiling statistics of this sort one cannot escape the indisputable fact that industrial medicine is preventive medicine practised on the firing line; that the daily supervision, the accessibility of the service to the patient, the frequency of observation, the early diagnosis and prompt treatment is the sanest and most economical way of preventing human wastage; that it keeps the front line of industrial attack and maximum production intact; that this is the best means yet devised for keeping the old time "evacuation stations" free from overflow of chronically incapacitated dependents; that to reduce the size of the human scrap heap most systematically we must move more of our scientifically trained medical men up to and on the industrial firing line.

We are digressing, however, too much from the immediate story of how these facts of industrial health work were presented to the public. The first two halftones accompanying this article show but two of the eight booths allotted to the industrial physicians for their display at the Health Exposition. However, they furnish to the reader the general plan of display of the educational material used throughout. The two shops shown sharply contrasted the clean, well lighted and ventilated conditions, safety guarded machinery in charge of a happy, efficient workman, with the dark, unclean, unhealthful, unsafe conditions of the bad shop, where a dissatisfied workman demonstrated what interfered with his efficiency. In the other six booths there were displayed in order a well equipped employment office, waiting or rest room, medical dispensary, laboratory and supply room, a surgical room, and, finally, a dental office. Here nurses, doctors, dentists, and employment managers made effort to satisfy the questions of the passersby. When the workman-spieler in the "bad shop" finished his talk he passed his audience on to the "good shop" spieler, who usually finished his remarks by pointing out the splendid facilities down the way, the nurses, doctors and dentists, which his thoughtful employer furnished him.

And so it went on from day to day

until the close of the exposition. Of course, there were numberless cases of good natured controversy between these two spielers and the passing public. Here came some employer who said that the bad shop as pictured did not exist in reality, and then occasionally a workman who said that the place where he worked was just as bad. Then in turn came several industrial leaders who were so impressed with the forcefulness of this exhibit that they forthwith sent out letters to the entire membership of organizations of which they happened to be officers, urging these manufacturers to visit the exposition and, particularly, this exhibit.

And so between the sparks of wit and emery, between the good natured sallies from the visitors and ready answers from the man at the machine, the explanations by doctors and nurses down the line—between all these and with the help of attractive line drawings of industrial subjects backed up by brief, trenchant statements on posters, there was brought to the public mind the appreciation that industrial medicine has added a new and positive factor to the science of the prevention of disease and lost time on account of accidents, and

Good Management and Good Health

Modern management knows it pays to spend annually \$5.00 to \$12.00 per employee to keep its working force physically & mentally fit.

The human body is the most valuable and delicate machine & should be conserved at any cost.

Preventable illness is a great drag on employee, management & society.

**INDUSTRIAL MEDICINE
Can Save This Loss.**

that better industrial relations is but its corollary.

The Making of a Radical

The thoughtless employer blames the labor agitator for most of the radicalism that appears in the ranks of labor, giving little thought to the fact that he may himself contribute largely to the prevalence of that state of mind. The employer is often prone to forget the enormous advantage that he holds over the labor leader in that he, through his organization, is in daily contact with the worker, whereas the radical labor leader's contacts are but intermittent. Too few employers appreciate that the unclean, unsafe shop where the foremen and executives drive rather than lead their men—where even the common garden variety of human considerations, comforts, and conveniences are missing—is also the shop where the men's minds are daily poisoned against organized industrial leadership and, conversely, opened to any other leadership that may offer. It is during the working hours of the day that men's minds are most alert and receptive, and it is important, therefore, that the impressions that are hourly being made upon those minds should be free from fair crit-

icism. Unnecessary and frequent accidents, preventable occupational hazards, thoughtless treatment of employees, wasteful methods of production, slipshod wage system, where the employee is unable to check his own earnings, are all factors that lead to disagreeable relations between the employer and employee and add to the age long gulf between labor and capital.

Better Citizenship

The Disarmament Congress at Washington is spelling a new era between nations and promises the release of billions of dollars, now used in the manufacture of instruments of destruction, permitting these sums to be used for the improvement of living and working conditions, along with educational facilities for the people of all the world. It may be said with equal truth, that if organized labor and organized capital could also be disarmed to the end that the ever constant strife between these two groups could be lessened, billions of dollars in added production, added earnings, would take the place of the enormous wastage that now occurs because of this constant strife. The conditions of industry, the relations between employer and employee, are a very fair index of the character of any country or community.

The individual employer too frequently forgets that his particular industry is but a part of the whole and that the character of relationships that exist between himself and his men leavens the state of mind that exists between the employing and employed classes of his community, and that the general quality of the citizenship of which his men are a part, is raised or lowered, depending upon whether his organization is producing happy, contented citizens.

It cannot be denied that clean working conditions, reasonable comforts and conveniences, a fair wage system, and considerate personal relations throughout the working hours, produces a state of mind, a shop spirit, a certain morale, that makes for a feeling of responsibility throughout the organization, an appreciation of the necessity for organization and the part that each must play in such. Out of this feeling of mutual trust and confidence there grows a respect, not only for the industry but for society as it is organized, and a better quality of citizenship is the net result. The consideration of the health of the worker is but one factor in the important per-

WORK HERE AND LIVE LONGER

A slogan that might be well adopted by many industries.

The proper physical care of the worker, the providing of good working conditions lead to better health stability of the industrial organization and a higher quality of product.

sonal relations program, but it goes a long way to help make men sane both in body and mind. Contented citizenship does not grow out of a populace which is suffering from unnecessary illness and injury. Many of the so-called grievances can be traced to a physical basis. Not the least satisfaction that should come to the intelligent employer in creating a good shop morale through these various methods should be that he also creates thereby happier contented conditions in the homes of his employees. And thus is effected an even wider circle of citizenship.

Care of Accidents

The dollars and cents value of the prevention of unnecessary accidents has been so thoroughly proved by the National Safety Council that little need be added in that direction. What the employer has failed to sense however, is that enormous savings can be made by the prompt and efficient treatment of all accidents as they occur and that the installation of medical departments in industry has long ago been taken out of the charity welfare class. The immediate attention to injuries by men especially trained in that work not only reduces the number of infected cases to practically nothing, but greatly shortens

Saved to these 11,800 workers \$265,500 in Wages.

the period of disability, reduces unnecessary pain, reduces the loss of wages, and of course adds to production.

There is some danger, now that industry has allowed a fixed charge in its budget to cover the cost of industrial accidents through Workmen's Compensation Acts, that it may henceforth regard its responsibility in this direction as closed. We do know, on the other hand, that a great percentage of accidents and their expensive sequelae are so largely preventable that these present fixed costs might well be reduced by one-half. Statesmanship in this country is not at a very high premium, but nowhere has organized society shown any greater weakness and incapacity to reduce unnecessary wastage than in the handling of these great state funds under industrial compensation commissions. It is time for industry to wake up and supply the leadership, the brains and the facts that will make of the state compensation commissions great social agencies for the prevention of accidents and proper treatment when they occur and thus save to society the present waste of men and money. One direct and immediate result of such intelligent organization would be the pre-

vention of the conditions that lead to occupational disease, their prompt diagnosis and proper treatment.

Leaving Home

A pen drawing showed the picture of a happy workman leaving his home in the early morning hours, waving "goodbye" to his wife and children. In Ohio, approximately four thousand such men each year wave their goodbyes to their families in the morning, never to return alive. Thousands upon thousands more are brought back home crippled for life and unable to care for their families, which, even though they receive compensation for permanent disability, are most likely in the end to become a charge on the community. In the same way five thousand dollars or six thousand dollars, as compensation for death on account of injury, merely cares for the family temporarily, but permanently takes out of the community a productive citizen who was not only providing for his family but was adding to the total wealth of that community.

Good Management and Health

The value of the prevention of illness and the value of life prolongation methods are so well accepted today that we can well judge the intelligence of governments—national, state and local—by the type of work that is carried on by them to assure their citizens freedom from contagious diseases. Millions are expended in protecting the food and water supplies and giving proper medical supervision to the growing child at school. A great many more millions however are spent in the erection and maintenance of hospitals largely used for curative work. Relatively little is spent by communities in an intensive application to the individual of the science of the prevention of disease or its early diagnosis.

The difficulty ever has been for society so to organize its medical supervisory forces as to make medical attention so accessible and convenient that individuals at large would apply for such medical attention at the incipient stage of illnesses. It has been practically impossible to educate the average man to consult the physician regularly for a physical examination that would discover any deficiencies that may exist and to correct them promptly so that they will not become permanent in their nature and thus interfere with his earning capacity.

With the establishment of the new specialty, industrial medicine, and the placing of the physician in industry,

medical attention has for the first time become daily and conveniently accessible to the adult. Intensive preventive medicine applied to the individual here becomes possible. It is sought out by 7 per cent of the working force each day in some industries. To supply such service costs from five dollars to twelve dollars per employee per year. The fact that the best managements in the country have continued this service indicates that it must pay for itself.

Modern management spends vast sums in keeping its machinery and equipment in a high degree of perfection. The human body of the worker is the most delicate and valuable machine in the plant. Upon its efficiency, physical and mental, finally depends the efficiency and output of the machinery and other equipment. Poor health is a great drag on the employee and management. It spells the idle machine, lost wage and production, and society is vitally interested in all three.

Good health, good shop spirit, good relations, and good management go hand in hand.

Organized labor has, in the main, raised objection to the making of

Messenger of Good Will

The industrial nurse an aid to the family physician.

Makes temperature and pulse readings, suggests suitable diets, instructs family in care and comforts of patient.

Keeps patient in touch with the men, foremen and the physician of the plant.

Her periodic visits may save the cost of a full time nurse.

physical examinations at the time of employment, claiming that too many men were thereby thrown on the human scrap heap. Further, that industry was largely responsible for the physical defects in individuals and that society must see to it that these individuals also be given a chance to provide for themselves; that the unfit must be carried along with the fit at the cost of industry.

Answer has been made to this position that labor gains nothing by being ignorant of its physical impairments; that the making of physical examinations is the first and fundamental step either toward physical restoration or proper placement in jobs suited to the individual; furthermore, that society gains in knowing the size of the human scrap heap and what factors contribute to it so that legislation and other steps may be taken to prevent human wastage.

Intelligent consideration however of the subject now brings nearly all of us to the view that the making of physical examinations is a decided step in the conservation of human life—that the mass of workers in any plant are entitled to the protection against the spread of contagious disease afforded by this practice, that the hazard of having operators of machines, cranes, and other trans-

porting methods subject to epilepsy, heart failure, or defective vision must not be tolerated.

Physical examinations by industry carry a serious lesson for the medical profession in that a very large percentage of the men examined report this experience as the first time that they had ever been completely examined by a physician. It is also a first time for them to become really interested in themselves as physical entities. With this physical examination comes a larger interest in the desire to know the real basis for any illness, an earlier seeking of medical attention, a greater willingness to employ physicians more frequently, and to submit to surgical and other procedure when necessary.

Work Here and Live Longer

When labor was scarce all manner of devices were used by industry to attract the worker, many of which were socially and economically unsound. The American workman fortunately has an independent attitude toward *coddling welfare work*. The present industrial depression unfortunate as it is, will serve a real purpose in eliminating the frills and furlowings of such welfare work.

In strong contrast to the useless welfare work is the real service that is rendered the worker and society in providing good working conditions, stability of health, the reduction of suffering and loss from disease and accident that usually attends intelligent medical supervision. The far-seeing employer has not scrapped the services of the medical department in these parlous times, but recognizes that the physician can make a real contribution to a better morale and the necessary higher output per man at lower cost, that is so greatly needed at this time. Work here and live longer is a sane democratic appeal to the best type of employee.

It is always exceedingly difficult, even hazardous, to try to translate the value of preventive medicine into dollars and cents. A large insurance company recently broke its silence and made the first definite statement as to the money and lives it claims to have saved because of its periodic physical examinations. In this study 5,987 individuals, who were carefully examined annually over a period of six years, were placed alongside a comparable group of a like number of policy holders who did not elect to accept this annual physical review in those six years. The company spent \$48,900 in periodic physical examination work and effected a gross

saving in death losses of \$126,477 and a net saving over expenses of \$77,577. The group examined show a mortality experience of 53 per cent as against the American experience table, and a 72 per cent record on the American Men table. It is shown that the mortality has been reduced at a cost of \$1.36 per policy holder per year, and that the net profit to the company on that expenditure is \$2.16 per year, or a gain of 159 per cent on its money invested in this work. Even in boom times 159 per cent is a handsome profit in industry. These figures merely suggest that if people are worth saving, society at large is overlooking some very handsome dividends.

Absence in industry on account of illness varies from 3 per cent to 8 per cent. Industrial medicine can reduce the absence on account of illness to 1½ per cent, perhaps even lower. Accepting the lower figure of 3 per cent as the normal and 1½ per cent absence as the attainable through medical supervision, we should save for each worker four and a half days of earning power each year. The 11,800 workers who made nearly 107,000 visits in 1920 to the seven industrial medical departments, were diagnosed early, sent home when in-

capacitated for work, advised to consult their family physicians, and where necessary, referred to specialists. These 11,800 workers, saving 4½ days each at an average wage of five dollars, would experience a total saving of \$265,500.

Abscessed teeth and infected tonsils, as the source of focal infections responsible for many chronic rheumatisms, lowered vitality and chronic illnesses, have received a great deal of attention on the part of the medical profession within the last few years. Many individuals by proper procedure in this direction have been restored to their former efficiency. The installation of industrial dentistry has provided some new comprehensive data as to the neglect of teeth by the average worker. Of the 3,300 employees examined in 3 plants, 45 per cent had never visited a dentist. The cleaning of their teeth by the industrial dentist, the pointing out of dental work needed to be done and the interest that was stirred in mouth hygiene was most valuable. In many cases it was the beginning of the workers' interest in personal hygiene. Here again industry is doing for the adult what school dental hygiene is doing for the child. Here again, the accessibility of dental serv-

ice to the individual brings the patient to the dentist far earlier than would otherwise occur, and thus preventive measures are made possible.

The intelligent, socially minded nurse should be a great force in better relations. Under wise management she is solely responsible to the medical officer of the plant. As such she will preserve all the best traditions of her profession and that of the medical men in her relations to the patient. She should possess common sense and initiative to no uncommon degree so that she may at all times preserve the best of good will between patient, plant physician and private practitioner.

The numberless records of observations made by the plant physician, his physical findings extending perhaps over years, his temperature and symptom readings just preceding the patient's acute illness should, through the nurse, prove of great advantage to the family physician. She can further assist him by such hourly nursing service as he may desire and thus hasten the patient's recovery. The nurse, through her daily visits at the home, keeps management and fellow employees apprised of the patient's condition. She will frequently serve him best by insisting on a prolonged convalescence when the patient might unwisely seek to come back on the job. She further may, in some instances, protect the patient's record in the shop from the suspicion that he has remained home for causes other than illness. Her many possible services to the wife and children in the home in the way of incidental instruction in matters of diet and other hygiene problems are beyond enumeration and may save the cost of a full time nurse to the family.

There are probably thousands of deserving ex-service men scattered over the country who have failed to prove their just compensation claims because they were unable to supply affidavits which set forth in detail their physical conditions previous to entering the service. Their condition of health after discharge and then upon entering their old jobs or professions were not noted by anyone except in cases where they applied for employment in industry where medical supervision and physical examinations obtained.

The average family physician rarely has complete data in the matter of physical examination, and unfortunately too frequently his prescriptions are written without entering a record as to symptoms and findings at that time.

SOLDIERS' COMPENSATION

The Government requires definite information of this kind in order to connect disability with service. These facts as well as the one that young men rarely take the matter of health seriously enough to consult physicians frequently, made it difficult in thousands of cases for the deserving ex-service man to bring proper proof to the Government.

The accessibility of medical service in industry has educated employees to concern themselves more frequently about their so-called minor ailments, with the result that there is a multiplication of medical observations and records in industrial medical departments away beyond that made by the private physician. A good deal of bad blood has been spilled by the ex-service man because of the endless red tape and delays which he feels has surrounded the Government's determination to get accurate data before allowing medical treatment, vocational training and compensation. The well organized industrial medical department made smooth sailing for many of the deserving applicants who had no other definite source of information on which to base their required affidavits.

Industrial Surgical Service—Past, Present, Future

Adequate Service Does Not Stop Short of the Utmost Effort Toward Functional Restoration

By J. ROLLIN FRENCH, M.D., LOS ANGELES, CALIF.

INDUSTRIAL surgery is rapidly becoming recognized as a specialty—justly so, and no doubt the so-called "Company Doctor" of the past will soon exist only in memory.

Not long ago, the idea was general that treatment rendered the industrially injured was for the express purpose of satisfying public opinion, little concern being given to rehabilitation and functional results. The "Company Doctor" was one who would accept the position at the smallest salary, and his main duty seemed to lie in speedily removing the patient as far as possible from the place of employment. It may be readily seen that in such a regimen there was little incentive to stimulate technic and modern means of therapy for functional rehabilitation.

Amputation was often recommended to shorten the period of treatment. The healing of the wounds and fractures was not followed by therapy of any kind, and the permanent disabilities were enormous in proportion. As a matter of fact, limited function was anticipated just as was "laudable pus" before the days of Lister.

Better Standards Develop

The compensation laws of today perhaps may be given credit for beginning stimulation in developing industrial surgery, and no doubt the recent war also added materially to the development of modern technic and therapy. Conservation of man power was a subject of greatest consideration, hence our eminent surgeons directed their attention toward the subject of rehabilitation with functional results, which gave us the foundation for our present therapy. Industries soon began to recognize the direct financial benefit of the better service, not only in the reduction of employment turnover costs, but in a diminution of the expense of permanent and prolonged disabilities, which had been automatically charged against the employment account in compliance with the industrial accident laws.

That the percentage of industries recognizing this fact is still comparatively small is, in my opinion, to

be charged directly at the door of too little stimulation along the line of better surgery in industry. Because of it, many employers are still laboring under the prejudice of the antiquated ideas of the past.

As above stated, rehabilitation was stimulated by the war, and as soon as the fighting was over and the patriotic duty had terminated, the advancement in reconstructive surgery was materially retarded by the surgeons returning to their civil practice. A few, however, continued with the work of rehabilitation in industry.

It may be that one of the greatest reasons why a greater percentage of surgeons did not take up the work of industrial rehabilitation was because of the stigma attached to the old-fashioned "Company Doctor." Not only to the medical profession did the "Company Doctor" signify the cheapest kind of medical service, but he was reluctantly accepted by the employee and was, at the same time, exceedingly expensive to the employer.

Exit the "Company Doctor"

The specialty of emergent orthopedic surgery, as pertaining to industrial accidents, was not sufficiently recognized to stimulate the interest it now commands. Fortunately, however, some of the better schools of medicine are recognizing the special applications of traumatic surgery and are now including industrial courses in their curricula. No doubt in the near future our post-graduate schools will be in a position to render industry a great service by offering graduate courses in industrial surgery, thus officially recognizing the specialty and automatically doing away with the so-called "Company Doctor," who has no knowledge of and little interest in the modern treatment of the industrially injured.

The demand for better treatment in industrial injuries is steadily growing more urgent, but, due to the dearth of special training in the past, this need has not been met. The efficiency of each organization has so far been limited to the initiative of its chief surgeon. In time to come, the results of the service will be expressed in units of service demanded,

classified according to the laws of the respective states, and in some degree influenced by the public opinion of the particular locality, and the attitude of the employer.

It is extremely gratifying to note that the employers are in most instances ready and willing to improve their service when definite facts demonstrating better service are presented.

Industry is dependent upon the reports of industrial surgeons for advice relative to the facts and physical findings of its injured. If such reports are rendered by surgeons who are not qualified by experience and training in this specialty, and lacking the necessary knowledge of law and contract, they are likely to be misleading, and in such event industry is either wrongfully charged with that for which it is not responsible, or it may be that the injured man is unjustly classified as a malingeringer.

Unfortunately, the term malingeringer has been used without qualification, and no doubt too frequently applied indiscriminately to patients who have not returned to work. As a matter of explanation, I will modify the term, defining true and false malingeringers.

No explanation, however, is necessary in the case of the true malingeringer; we know he is encountered, though not nearly as frequently as is often accredited. Not seldom does a careful analysis of a so-called malingeringer result in the disclosure of many facts that have been overlooked by inexperienced or unqualified investigators, and that further treatment is in reality necessary. In the past it has been generally assumed that a man should return to work as soon as his wounds were healed, and no responsibility was assumed for subsequent treatment to bring about the best possible functional results.

The false malingeringer is frequently seen and he presents one of the greatest problems associated with industrial injuries. I refer particularly to a false interpretation of existing symptoms: for example, the surgeon may be right when he advises a patient to return to work, but, because the surgeon does not deem it necessary to give the injured man a detailed ex-

planation of his case, the latter refuses. The patient groundlessly anticipates that by following orders he may do grave bodily harm to himself instead of achieving a complete restoration of function. These patients are materially benefited by occupational therapy. In other words, a survey of the mental attitude of the patient reveals the fact that he has the idea that if he returns to his usual occupation, detrimental results will follow, but if concessions are made and certain work is prescribed as a part of the therapy in his case, he will willingly do as directed. It may in some cases be necessary that his duties be camouflaged so as not to seem a part of his regular work.

Interest is Enlisted

Occupational therapy seems to be the only practical method of camouflaging work. Unfortunately, few authorities seem to recognize this point, which, in my opinion, is the link between success and failure in a large percentage of cases, and must be administered with a sincere desire to stimulate the cooperation of the patient.

In prescribing occupational therapy, one of the principal points to bear in mind is the practicability of the prescription; in other words, it must be ascertained in what the patient is interested. If the patient has a child at home, he will probably manifest enthusiasm in making a toy; or a young man might be readily induced to weave a dresser scarf for his sweetheart; or a devoted husband interested in making some bric-à-brac to beautify his home. On the contrary, however, if work is prescribed which is not of interest to the patient, cooperation is frequently wanting and the results are far from pleasing. The prescribed work should always be something which exercises the injured member. The lack of proper discrimination on the part of the surgeon results in poor treatment. It is just as important to have the ability to treat psychic disturbance as it is to have the proper technic for actual surgery, and until this ability is inculcated in one and the same person, or in one and the same organization, the problems of industrial treatment will not be solved.

In the past there has been no organized effort toward the systematic treatment of the industrially injured by any means other than the routine surgical procedures and massage. Many of our larger industries have developed their surgical service to a

degree of perfection, but the efficiency of the department is materially handicapped because they are satisfied to confine their work to the surgical unit. Custom and satisfaction with a partial service are the greatest stumbling blocks of progress and efficiency.

In many instances cases drift into the hands of unskilled doctors and are not called to the attention of a skilled organization until the basis of a permanent injury has resulted. Unfortunately, all doctors "look alike" to the layman, and not infrequently the doctor builds up his business by eloquent oratory instead of proving his merit by the functional results obtained.

In some states, through their compensation laws, it was held that the injured employee was greatly favored by permitting him to choose his family physician. As a matter of fact, such measures actually wreck the intent of the law by encouraging less efficient treatment. In other words, there is no incentive in such legislation for the employer to develop systematic treatment and thorough organization.

It is indeed a pleasure to visit the hospitals and surgical departments of a few of our industries and note the results of modern therapy, stimulated through the sincere desire to put into practical application the intent of industrial laws, and a survey of these organizations demonstrates the financial return to these employers.

Problems in Small Plants

One of the greatest problems of industrial treatment today is the care of the injured from the small industrial organizations, who are not individually able to maintain a complete medical organization. The industrially injured of these corporations frequently suffer for the want of proper, organized treatment. The cost to maintain service in the individual plants would be prohibitive, but by cooperation and establishing a centralized organization the same efficient service may be rendered.

Surgeons frequently differ relative to the surgical treatment appropriate in an individual case, and not infrequently criticize each other upon certain methods of a surgical operation, or remedies used in treatment. Such differences of opinion, however, are only a matter of detail and we must remember that there are not infrequently two roads to a given point, and perhaps both are equally good. Avoiding this detail, I wish to present a logical outline for organized and

systematic treatment for the future.

One of the first problems confronting us is the atmosphere of prejudice propagated by an employee against the medical treatment offered by his employer. Many of the older employees have memories of ill treatment that was by no means imaginary on their part. This, of course, has automatically reflected upon all company service, has operated to prevent a larger percentage of the better surgeons from identifying themselves with industrial surgery.

The compensation laws of some states have grasped this situation and perfected a remedy—namely, to give the employer the opportunity to furnish efficient medical treatment and demand that the employee accept same unless good cause for refusal can be shown. This gives an opportunity for employers to build up a splendid treatment organization, with the result that the injured employee receives the best possible treatment. When the employer fails to render proper treatment, the employee may seek treatment at the employer's expense; thus, the employers who conscientiously intend to render better treatment, may be protected. At the same time, the employee is protected against that class of employer who gives little or no thought to the personal feelings of the employee, or his future physical efficiency.

The question invariably arises: "What is adequate treatment?" The attempt to answer this query usually results in a discussion of the relative merits of specific operations or treatment, and because of pre-existing prejudice, the employee questions the motive of the medical organization of the employer. As soon as the employee is educated to the fact that the employer is conscientiously tendering the best service, these petty arguments will automatically be eliminated, as has already been demonstrated by the employers who are rendering the best service.

Adequate treatment can only be defined as complete service. Service does not necessarily signify luxury, but should signify every reasonable consideration from the time of the accident until the employee is reasonably able to return to his usual, or some other remunerative employment. It is the application of this principle which will represent the service of the future. The only way this can be properly accomplished is through the sincere and conscientious efforts of a qualified industrial surgeon, unhampered by laymen's selfish opinion, and through an efficient medical or-

ganization, departmentized so that the treatment of the individual injured will automatically be referred to the department which can accomplish the most toward functional rehabilitation.

A Case in Point

To illustrate this point: A competent surgeon may operate a case, but because organization is wanting, massage and occupational therapy are delayed until the service of the surgeon has been completed. This, in many instances, is too late to obtain the best functional results. In such cases the surgical treatment should be supplemented by the work of other departments before the surgeon's dressings are ready to be removed. It follows that, if the surgeon has not at his command the necessary correlated departments, the functional results for the patient will be impaired even though the operative procedure was successful.

Good surgery does not represent more than one-third of what may be considered as adequate industrial accident service. When this fact is more generally recognized, therapeutic organizations will be departmentized, each specializing in its respective service. Such units of service, however, are not practicable unless there is a volume of work of a given kind. On the other hand, cases in sufficient numbers to justify such service will not be forthcoming until the industrial work of the community is centralized. This will not take place until the need, and the efficacy of physical therapy have been demonstrated through thorough organization. If better treatment is instituted through thorough organization, cases will then be segregated and referred in sufficient numbers to justify the special services necessary.

The treatment of the future will include every practical means of assisting the industrially injured to a speedy recovery, which will permit reasonable competition in earning a livelihood. In addition to the surgery, which includes the reasonable allied branches, such as ambulance service, hospital, subsequent dressings, etc., we must welcome every possible means of assistance to further this end. Practical exercise and training, occupational therapy and social service work, and, in some instances, re-education, are all stepping-stones to ultimate recovery.

If the reconstructive surgery, supplemented by proper subsequent therapy, is conscientiously adhered to, comparatively few cases will call

for re-education; hence practical social service work will supervise re-education through the schools which already exist, either private or public.

Practical results can be estimated only by a survey of the individual cases. In many instances, a psychological diagnosis, supplemented by practical treatment, either psychic or physical, will contribute as much, if not more, than surgery toward establishing functional results.

Compensation features must not be overlooked, which may include the proper reporting of cases and prompt payment of compensation benefits. Attention to this detail adds much to the service and assists in preventing neurosis. It can be readily perceived that the prompt receipt of compensation and other benefits tends to preserve a proper mental attitude and eliminates the possibility of the patient becoming a victim of worry concerning the maintenance of himself and family. When the patient receives prompt attention with regard to his benefits, a spirit of cooperation is promoted, with the result that convalescence is usually uneventful and not unduly extended.

Service Twofold

While organization for the treatment of industrial injuries will be maintained presumably for the express purpose of rendering service to the industrially injured, it must not be overlooked that there are certain services which are due the employer in order to protect him from the malingerers. In rendering this service, not only is the employer served, but the morals of the employee are safeguarded by limiting the bragging propensities of the malingerer of his success in obtaining money under false pretenses.

In organization lies the only hope for better treatment. This automatically standardizes routine and necessarily stimulates closer attention to detail. It is this minute attention to the combined findings of the various departments carefully recorded, which assures an accurate diagnosis, and renders treatment only a matter of application of surgical skill, supplemented with various forms of modern therapy to assist in accomplishing functional results.

The treatment of the future will result in the discarding of customs which have become antiquated and consist of applied standardized routine treatment made possible by organization. It will incorporate all modern therapy which tends to assist the injured member to an early re-

turn of function, not overlooking psychic as well as surgical treatment. Experience is witness to the fact that diplomacy on the part of the attending surgeon frequently adds as much to the functional results as other actual treatment.

The surgeon in charge must have a constructive and susceptible mind, capable of weighing the hundreds of problems which confront him. Not only must he have the ability to suggest the treatment which is applicable to the particular case; he must also be able to make a psychological diagnosis of the antagonistic patients and be resourceful enough successfully to change the mental attitude.

These qualifications must be manifested in one and the same person, or one and the same organization, to accomplish the results anticipated in the future.

Formulates Program for Preventive Medicine

In formulating a tentative program for preventive medicine, Sir George Newman lays down ten principles: eugenics, maternity care, infant welfare, health of the school child, general sanitation and hygiene, industrial hygiene, prevention of communicable diseases, prevention and care of non-infectious diseases, public health education of the people, and research.

With reference to eugenics, he places its principles at the beginning of all effort. Environment, infection, accident and disease all have their effects on man, but it is his own body that must furnish the basis of health. His body should be sound. Since heredity cannot be ignored if we are to grow a sound and healthy race, the breeding must begin, where all breeding begins, at the source. "If we permit ourselves," says this great English administrator, "to favor and provide for the unguided propagation of a population of poor physique or of persons marked from birth with the stigmata of alcohol, venereal disease or mental deficiency, we shall sooner or later discover that we are building on false foundations."

A complete plan for maternity care should include: adequate medical, midwifery and nursing service, sufficient and satisfactory nourishment for the mother, maternity centers, maternity home and hospital facilities, domestic aid, maternity benefit and, if need be, financial aid and notification of births, including still births. The problem is vast in the application of remedies, but these are important in the rearing of a nation that is to hold its own.

Recent Compensation Decisions

THE matter of posture during work and resulting neuroses has been passed upon recently by the Supreme Judicial Court of Massachusetts. In the case under discussion the employee was a cigar maker. Early in 1918 he began to have pain in the region of the back of his neck, and in February or March, 1919, he consulted a physician who told him that he had to give up his work. The entire opinion will not be given here. The decision rests on a previous case, *Maggelet's Case* 116 N. E. 972.

While the Board found that the neuralgic pain was induced by muscular action in rolling cigars for a number of years, the impartial physician testified that any other occupation was likely to cause the pain from which the employee suffered, and that this condition could result independently of any occupation. In view of this, together with all the other evidence, we are of the opinion that the pain could not have been found to have been a reasonably necessary result of the employment, and cannot be said to have been a personal injury peculiar to it. We are also of the opinion that there was not sufficient evidence to warrant a finding that the employee had neurosis—a disease with which cigar makers are sometimes afflicted—and the impartial physician so testified; nor is there evidence that he had any disease, the reasonable inference being that the neuralgic pain was not due to his occupation, but was rather the result of faulty posture brought about by long and laborious work, a condition which would have been equally liable to arise in whatever employment he might have been engaged, or if not employed at all.

The Court goes on to say:

If it could be held that the employee was suffering from an occupational disease, still the Workmen's Compensation Act does not in terms include disease. (Stat. 1913, C. 813, Sec. 12). It cannot be held to cover disease contracted by employees in the course of and arising out of their employment. Pain is not disease, nor is disease resulting in pain a personal injury.

Acts 1913 C 813, Sec. 12, Subd. d. reads: "The terms 'industrial disease' and 'occupational disease' shall mean and include any ailment or disease caused by the nature, circumstances or conditions of the employment."—*Pimental's Case, Supreme Judicial Court of Massachusetts, May 22, 1920, 127 N. E. 424.*

WHERE an engineer died of heat stroke suffered while in the heated engine room during working hours on a hot day, death was caused by an accident arising

out of the employment within the Workmen's Compensation Act according to the Supreme Court of Illinois. In the opinion of the Court:

The Commission made findings that the deceased, while in the performance of his duties, suffered a heat stroke which was superinduced by the excessive amount of heat in the room in which he was working, and there was evidence to sustain its findings. The heat stroke occurred in the course of the employment, and there was evidence from which the Commission might reasonably conclude that it arose out of the employment. The man was overcome by the heat in his employment, and because of it, he was exposed to a degree of heat beyond the ordinary temperature of the day. While it cannot be demonstrated that he would not have been overcome if he had not been at work, the fact is that he was overcome under circumstances which furnish an adequate cause for that result, and neither the commission nor the Court will indulge in conjecture as to what might have happened under other circumstances. He might have died from the heat of the day if he had stayed home, but he did not, and he did die from the heat of the day and the additional effect of his work and the artificial heat of the engine room.—*City of Joliet v. Industrial Commission, 26 N. E. 68.*

A PAINTER who was standing on a ladder, fell suddenly as a result of an attack of vertigo. The Appellate Court of Indiana has held that the injuries causing his death resulted from an accident "arising out of his employment and not from a disease," and compensation under the Workmen's Compensation Act was held to be allowable. The Court further remarked here that where the Industrial Board has found that the death of an employee was the result of an accident which arose out of the employment and was within the Workmen's Compensation Act, this finding will not be disturbed by the Courts where there is evidence to support it.—*Board of Commissioners of Green County vs. Shertzer, 127 N. E. 843.*

THE Supreme Court of Iowa has held recently that although a bruise arising out of and in the course of employment was slight and would not have resulted in prolonged disability except for the fact that the claimant had latent gonorrheal trouble, where evidence is submitted that "hidden gonorrheal trouble can be lighted up by a bruise," a finding that the injury was the proximate

cause of the disability was warranted. The Court said in this case: "What is claimed for is injury as inflicted by the accidental slipping of the hammer and the natural consequences flowing therefrom and traceable thereto, and, as said, this might have been found by the Industrial Commission to be the lighting up or accelerating of a dormant disease. The claim is not passed on the disease, but on what the bruise did to the disease."—*Hanson v. Dickson, 167 Iowa 66; 176 N. W. 823.*

THE California District Court of Appeal made the following decision and a hearing on the case was denied by the Supreme Court September 1, 1921. In view of the two cases just quoted, the logic of the distinction "arising out of employment" may be questioned. The Court in this case dismissed the matter of horse play, holding the cases not pertinent where a claimant was injured in the scuffle with a subforeman who was acting outside of his authority in attempting to discharge the claimant, the injury did not arise out of employment, so as to warrant an award of compensation.

The facts of the case are stated in the findings of the Commission. "Applicant was one of a small group or gang of high school students hoeing weeds under hire of defendant city during vacation, under immediate direction of Frank Wood, a student of about the same age as applicant; that said Wood did not have authority to discipline or discharge any member of the gang, and applicant so understood; that said Wood under pretense of same authority, purported to discharge applicant for some alleged breach of rules, and attempted to take away from applicant the latter's hoe, Wood being entirely the aggressor; the applicant resisted, and in the ensuing scuffle he sustained injury to his left ankle. . . ."

The Commission granted an award of \$106.81, which was annulled by the Court.—*City of Pasadena v. Industrial Accident Commission of California.*

A SCHOOL teacher, carrying on chemical experiments prescribed by the Education Law, is not engaged in "hazardous occupation," within the meaning of Workmen's Compensation Law, under Const. Art. 1, Sec. 19.—*Boeman v. Board of Education of Penn aYn, 187 N. Y. S. 213.*

The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents

The Work of Fatigue Elimination in Colleges*

Pioneer Work in this Field Was Initiated by
Professor George F. Blessing at Swarthmore College

BY FRANK B. GILBRETH AND L. M. GILBRETH, MONTCLAIR, N. J.

AS EARLY as October, 1917, Professor Blessing wrote us telling of his interest in Fatigue Elimination day and of his plan to celebrate it at Swarthmore College, where he was Professor of Engineering. This was the start of what was up to the time of his death a most wonderful participation on his part in Fatigue Elimination work. On the first Monday in December, Professor Blessing carried through the first Fatigue Elimination Day at an American College. At the December meeting of the American Society of Mechanical Engineers he told us of the interest taken by the students and the faculty in the plan that he worked out, and later, at our request, wrote us a description of what was done. We quote his letter to us dated January 1, 1918, accompanying the short informal manuscript which shows his inherent modesty and explains his writing the article in the third rather than in the first person:

Under separate cover I am forwarding you some rough notes on the work we did at Swarthmore College December 3, 1917. I have tried to put the matter in a rather popular form and in such shape that you can easily recast it into a story for the *Independent* if you consider it of sufficient value.

You can see that it is difficult for me to write the story of Fatigue Elimination Day at Swarthmore without figuring too prominently in it myself to be the author of the article. I do believe, however, that good can come out of what we did if it can be given proper publicity. Other colleges are sure to take it up and the

educational world is not without its influence.

I believe I am doing pioneer work in giving the "Human Element" a prominent place in an engineering course. . . .

We found his story of great value, but at that time the popular interest in fatigue elimination was not sufficient to have this value generally accepted. However, we make no apologies for printing the article now. It speaks for itself. It illustrates not only what can be done simply and quietly and without expense to mark Fatigue Elimination Day and to hold the attention of an entire college, but it illustrates also the sincere, modest, practical character of the man and the vision which made him see that the little start he made at Swarthmore would grow into the big thing that the Fatigue Elimination Movement is today.

No monument to a man is as great as the memory of the good deeds he has done, and it is in order that the memory of Professor George F. Blessing's work for Fatigue Elimination may live that this article has been incorporated in the Proceedings of the Society of Industrial Engineers of whose Committee for Fatigue Elimination he was an honored member.

The Story Follows

The public is more or less familiar with the part played by athletic contests, fraternity dances, and pink teas in offering an outlet for excess energy on the part of a certain class of college students who do not find it necessary, or else have not the inclination, to give the professor and

his intellectual specialty all they have.

Students of the "motive" type seem to be so constituted that they require some "outside activity" to put a side of their nature on trial that studies do not reach. They crave something with more of the human touch to it than lectures and text assignments. Also, it must test out their managerial ability, and give them the complete responsibility for failure or success.

To meet this demand and so direct the students' energy into legitimate channels, the college authorities have looked favorably upon the many "student activities" that the public are sometimes inclined to criticize, as being a waste of energy and without educational value.

The fact probably is that one reason that college hazings, midnight raids, "beer busts" and immoralities have very largely disappeared from American College life is due to the college authorities encouraging almost any activity that keeps the student within reasonable and honorable bounds.

To make a college function, however, out of an industrial movement comes somewhat in the form of an innovation. Yet this is what recently took place at Swarthmore College.

It happened that one morning in the latter part of November (1917), the Professor of Engineering at this institution addressed the students at the morning devotional exercises on Fatigue Elimination Day as adopted by a number of industrial concerns throughout the country. At the conclusion of his address he stated that

*Read before the society of Industrial Engineers as a part of the report of activities of the Committee for the Elimination of Unnecessary Fatigue.

his class in "Social Engineering and Industrial Service" would, on patriotic grounds, join hands with industry, and, without interfering with classes, would observe December 3 as Fatigue Elimination Day by making a Fatigue Survey of the college as an institution, and by preparing an exhibit of fatigue eliminating devices to be placed in the Engineering Library.

Later, when the person in charge of arranging the exhibit asked Professor Blessing for something to start the exhibit he was given a worn pair of rubber heels and a home made alarm clock device for turning on the draft of the professor's furnace. The thing was started, however, and the whole idea seemed to take strongly with the class, the result being that in a very short time the "motive men" and women,—for this class is open to women—were planning, working for, and looking forward to Fatigue Elimination Day as though it were of as much importance as a football game, a dance, or a Soph. Show. The survey was turned in as a report in the class in "Industrial Service," and it included a study of the student himself, as well as of his most liked and disliked professors. Always, however, the spirit was very constructive, as this had been very clearly pointed out as the necessary element in making the work a success.

They Catch the Spirit

The Junior students in Mechanical Engineering looked up fatigue eliminating devices, and then designed and made such as they considered would fit their own cases. The Freshmen in shop courses made several Gilbreth fatigue eliminating chairs for the exhibit. Letters were written to makers of efficiency and fatigue eliminating equipment telling them of the exhibit, and inviting them to send samples of their product for exhibition purposes. Considering the rushed and unsettled condition of business, the response to these letters was surprising. A number of firms with branch offices in Philadelphia asked for the privilege of sending representatives to demonstrate their wares, and this request was granted in about half a dozen cases, with the understanding that no orders would be solicited. This, however, was unnecessary, as the equipment was not of the character that the student would want to purchase at the present stage of his career. These companies were looking to the future, for, as one representative said, "Our company realizes that the college students of today are the purchasers of tomorrow."

On the morning of December 3, at the morning Assembly, Professor Blessing again addressed the student body, explaining in detail how fatigue affected the worker and what had been done to eliminate unnecessary fatigue. Gilbreth's seven causes of unnecessary fatigue were given, and illustrations as to where they might apply to the students' life given. At the conclusion of the address it was announced that the Fatigue Elimination Exhibit in the Engineering Library would be open to visitors throughout the day.

As one entered the library referred to, the first thing that met his gaze was three advantageously placed flags, and beneath a well lettered legend, "Patriotic Duties."

FOOD IS THE FUEL THAT PRODUCES HUMAN ENERGY—SAVE IT.

UNNECESSARY FATIGUE IS THE WASTE IN THE HUMAN POWER PLANT—ELIMINATE IT.

HUMAN ENERGY WILL WIN THE WAR.

Below this was, "GILBRETH'S SEVEN CAUSES OF FATIGUE":

- (1) Confusion of issues. Define them clearly.
- (2) Improper assignment of work. Reassign.
- (3) Poorly distributed rest periods. Study them.
- (4) Bad working conditions. Clean them up.
- (5) Inappropriate clothing. Change it.
- (6) Lack of anti-fatigue devices. Procure them.
- (7) Lack of public interest. Arouse it.

No sooner had one read this legend than he was taken in charge by an instructor of the department who marched his group to a point where fatigue charts were displayed. Here the nature of fatigue was explained, and the fatigue cycle was shown by means of a chart,—how, in the beginning of work, during the "warming up" period, the working power at first diminished and then picked up until it reached a maximum value, which was sustained during a certain period of time, after which the working power dropped off rapidly unless at the proper time a rest period was taken. It was then pointed out that if this rest period was properly determined and used, the working power returned to practically its original condition. "This," said the instructor, "is what Dr. Taylor did with Schmidt, when he caused him to carry forty-seven tons of pig iron a day instead

of twelve and a half, and sent him home less fatigued with his big day's output than the small one." "Don't waste any sympathy on Schmidt," he cautioned. "You remember how it was done. Now pick up a pig and walk. Now sit down and rest. Now walk, now rest. You see every time his energy condition reached this point on the chart he was told to sit down and rest, and if you understand this chart, and how Schmidt was raised from a twelve and a half ton capacity to a forty-seven ton capacity you understand one of the big principles of scientific management."

Fatigue Curves

Then curves showing how fatigue compounded throughout the work and throughout the day were shown. "Those week-end parties don't do a thing to us," a student was heard to say, after looking over the weekly compounding curve. "I understand now that science backs up the coach when he makes us work out before taking another fellow's place in the game," said another. "Yes," repeated yet another, after having the fatiguing effect of noise explained, "there's going to be less noise during study period in our section of the dormitory from now on, or trouble for the rough-houser."

The effect of bad lighting and examples of good and bad lighting arrangements were shown. A fine collection of shades was brought on from the electrical department, and the Professor teaching illumination gave a talk with demonstrations. The effect of pure air in overcoming fatigue was told, and home made ventilators that gave ventilation without draft were on exhibit. An efficiency desk was explained and demonstrated by a representative of the maker, who also answered the students' questions as to how to eliminate confusion, systematize their desks and do their filing most efficiently. A properly arranged book shelf served the double purpose of showing how the student should avoid confusion with his books, and also gave an opportunity to look over six or eight books on Fatigue. A table contained many simple devices to act principally as hints for the student in eliminating unnecessary fatigue in his every day tasks. One especially interesting feature to the engineering students was the mechanical computing section, they realized the fatiguing effects of the ordinary arithmetical operations, and appreciated the value of mechanical aids. Every mechanical computing device in the department from loga-

rithmic paper stunts, slide rules and computing watches to electrically driven computing machines were on exhibit, and demonstrated by an instructor. Besides these, four computing machines were on exhibit, and demonstrated by a representative. It was found that as soon as an Engineering student had an hour free he returned to this section, and many and heated were the arguments they held as different ones championed different makes of machines.

Much interest was displayed over a well arranged lot of photographs il-

lustrating the experiments of the Gilbreths, wire models to illustrate chronocyclographs were shown, and several forms of chairs came in for many trials and much discussion. Professor Blessing, in talking of the exhibit, said that it had proven several things: First, that students will take an interest in an outside activity that connects their college life with industrial life as readily as in one that has very little practical or educational value. Such efforts have a tendency to vitalize the work of the class room, and many valuable les-

sons could be brought into the college life from industry by this method. It causes the student to think more seriously of his college education, as a preparation for life, and gives him something besides athletics, dramatics and social affairs to discuss during his hours out of class room. Business houses are glad to cooperate in such work.

Fatigue Elimination Day now has a permanent place on the Swarthmore College calendar. It is a full size college function! Efficiency has acquired new interest and a broader definition.

Process of Building Up Our National Resistance

The Neural Strain Incident to School Life Removed by Open Air Conditions

By WILLIAM E. WATT, A.M., PH.D., CHICAGO, ILLINOIS

WE KNOW what happens to a kitten in a sack with a stone when dropped off the bridge. We have our opinion of a family in the slums who let the baby get a high temperature before calling the doctor and then fail to follow his advice, although the father seems to have a clear conscience when he says, "God took 'm."

The usual schoolhouse is overheated and lowers resistance so that some children die quickly, some are doomed to a life of misery, and some merely blanch and weaken. Is anyone responsible for death when it comes from doing the usual thing?

No intelligent mother now attempts to bring up a babe indoors. She gives it fresh air—porch sleeping by day, use of cab, walking, riding—and cold air at night. There is no question as to the benefit. In advanced cities there is the fresh air room in the public school, with costly equipment of Eskimo suits, foot warmers, special feeding, sleeping chair, etc., for anemic and pre-tuberculous pupils. There children hurt by school recover strength, health, and vivacity until they are returned to the regular schoolroom. Of course there are not accommodations for one-tenth of the children who need it. There is a long waiting list of sufferers.

Arid Conditions Indoors

Open-air is generally prescribed for children and adults who are unable to cope with the conditions in home and school when heat is applied. Either the patients go out-

doors and brave the rigors of winter or they travel to some region where they may be warm and live outdoors day and night.

Yet with all this knowledge of what open, natural air does to benefit mind and body, the bulk of our citizens are dangerously weakened by the aridity, overheat, drafts, dead-air pockets, and other insanitary conditions of bad indoor air, even in supposedly perfect ventilation.

In the fall they come back from vacation in the country or in the city streets and alleys where red blood has been made and vigor accumulated, and enter school. In the spring all

are weakened, some have succumbed to disease, some are seriously enervated and the general alertness of all has been greatly impaired. Many fail to make their grade. Their grief is made more poignant by publicity. The teachers must spur them on! They tell the world—the child's whole world! And nobody seems aware that natural air would in most cases have averted the catastrophe.

Some Run Away

In spite of the many excellent qualities of modern education, it often happens that the child who has stamina enough to run away from school

This shows the disposition of window openings in the corner by a warm, open-air assembly room.

and keep out of the smell of overheated air is a gainer in the long run, although the law pronounces him a malefactor. Many children never see a well day after the fans start in the big schoolhouse. Glands swell and suppurate, stomachs balk, nerves get jumpy, night terrors are frequent, and many bright children are led to believe they are dull—born short—unable to do the stunts of their grade. Yet give these children air and they begin to live again. The school wilts them, but they can be resuscitated, if taken in time.

Children are not the only sufferers. Few teachers—very few—are sound after twenty years in school air. Life insurance companies put teaching down as a hazardous occupation, next to salcon-keeping and marble-cutting.

Resuscitations Made

We took a group of pre-tuberculous and anemic children to a vacant school lot one summer. A tent, sleeping-chairs, and food were provided. Teachers were paid to entertain them. We told the children their minds would gain strength with their bodies and, if they wished, the kind teachers would help them understand the school things that were hateful to them.

In five weeks those children gained knowledge so they were promoted when they returned to regular school in September. The average gain was six months of school work. Knowledge which had been too high for them became simple. Instead of trying to spur weak children on to more

Work under natural conditions is exhilarating. Physical stunts outdoors between intellectual stunts indoors are a safe procedure.

endeavor, why not fill them up, energize them with good air, and let Nature spur them?

Then we opened two fresh air rooms in a public school—fresh cold air. Pupils were not to have foot-warmers or feeding, but were to be allowed to wear caps and mittens in school and furnish their own warming by games of activity. They were frequently taken outdoors for these. They grew roses in their cheeks while pupils in "perfectly ventilated" rooms grew sallow and listless.

I have the written requests that

came to my desk like snowflakes asking that more than one thousand children in various grades be given cold air. Gradually the whole school became cold-open-air, except one room in each grade. We built two canvas rooms on the roof and kept them specially cold. The lower the temperature the better they liked it and the more they thrive.

Conduct was better. After seven months our records show that no cold-air pupil had been sent by a cold-air teacher to the office for rebuke for bad conduct. But plenty of help had been given warm-air teachers in dealing with cases of discipline in warm-air rooms. Scholarship was improved.

Big Boys and Big Dunces

Several big fellows were transferred to this school because they could not make their grades in their home localities, but wished to try real air. The case of one is typical. Every fall he had entered school and done well till the fans began to run and then his neck glands swelled and suppurated. His neck was a mass of scars. He explained that the doctor had cut off pieces with his scissors so it would look better.

The boy could not do fourth grade work in a modern high class schoolhouse. I put him at once into a fifth grade room, although he demurred because he had been made a fool of quite enough. He began in November; in December fifth grade was too easy; we promoted him to sixth—cold. He cleaned up the major part

Exhaling. Muscularity and an increase of chest expansion are promoted by these bending and stretching movements.

of that grade in a few weeks, mainly by reading it over, and went to seventh grade. He did not miss a day or a minute of school time. Other years he had missed more days than he was present after the hot air was being delivered. Many pupils made great progress. All were benefited.

Open Air for All

Then we set about getting outdoor conditions into indoor air without the chill. It is unnecessary to have the rooms cold. We evolved the warm-open-air school. This uses the gentlest heat that will satisfy all. Any heat in excess of what is necessary for comfort is too much. The heating plant is the enemy where there are stuffy rooms. We humidify and admit live, unwarmed air in very small quantity. Rooms are inviting and invigorating, but not cold.

We burn less coal. The small cost of getting rid of the air sewage without permitting it to mingle with the air of the breathing plane is soon returned in fuel saved. All are comfortable without extra equipment. Care of the building is reduced and there is nothing to get out of order. Whole cities have adopted it and their children and teachers are made glad. Teachers are less wearied by a whole day's work in natural air than they formerly were by the first hour's efforts. In fact, many were formerly more weary on arising in the morning than they now are at the close of the day!

The Nation's Peril

The hot bath which was such a factor in the destruction of the Roman empire was no more a national menace than the overheated air of the great majority of our school-houses in America. Read the thermometers in any school with approved ventilation or none and you will find practically all rooms overheated.

The New York State Commission on Ventilation says that temperatures between 68 and 75 degrees induce a strain which adds twenty-three pulse beats per minute, while the body averages 1.5 degrees above normal. In schools of all grades from kindergarten to college I have results of tests showing that no student can do as much accurate work in a minute or a day when the temperature is over seventy as he can do when it is under 68. The difference in efficiency is between 30 and 100 per cent when the air admitted is rightly conditioned.

Since ordinary schools are produc-

ing fever daily in the bodies of pupils and compelling them to work under conditions which militate against success, it is time to insist on a healthful state of the air where children spend so many hours.

Children can be out of doors half the day and do in the other half

quite as much as they formerly did in a full day indoors. School grounds are better used. Childhood is getting a better chance at life. Not only are the little folks doing their educational work with greater ease and more enjoyment, but they stand a much better chance to grow up.

Cornell Opens Pay Clinic

SO MUCH has been written arguing for health supervision, for the periodic physical examination, and on the symptomatic picture which marks the curable stage of disease, at which time the family physician should be consulted, that, naturally, questions have arisen as to what percentage of the people do have medical service, for what conditions physicians are ordinarily consulted, and which groups, if any, suffer from neglect.

Naturally, the public and private welfare activities which have multiplied so rapidly throughout the country have had as their object, service to the socially unfortunate. There has been no dearth of agencies, and, for the most part the best of medical skill has been available in the free clinics.

But the feeling of pride of achievement in the phenomenal growth that has marked child caring stations, school clinics, free dispensaries, and health centers must be modified by the fact that anything approaching what may be considered as adequate medical service reaches only the two economic extremes, the very rich who can command the best, and the hopelessly, helplessly poor to whom help

must be extended. Proof came in from many quarters that the present day methods of group physicians involve costs which are prohibitive to

Keystone View Co.

Charles F. Neergaard, director of the clinic.

the great masses of the people. Classified according to income in studies of disease prevalence, it was found that many family budgets in many cases afford no margin for medical care. Studies in infant mortality indicate that the mortality rate among the babies of unskilled work-

Keystone View Co.

Patients enrolling at the newly opened Cornell University Medical College Clinic. Here at the desk they cite their history, pay their fee, and are sent to the department for which their case calls.

ers is almost exactly double that among the skilled.

On the basis of these studies the fact must be accepted that relative poverty has prevented great masses of the people from employing skilled aid when in need of medical care. When facilities are lacking or not available to the masses, a lapse in preventive measures or failure to take "a stitch in time" cannot be charged to indifference of the people or even to lack of information. The stoical patience of the masses against the ills that could at least be lessened is one of the most pathetic spectacles of human life.

A Far Seeing Enterprise

Cornell University has risen to meet this need in establishing a "Dollar Clinic," designed for those who cannot pay the office fees of specialists and yet do not wish to go to a charity clinic, was opened recently at First Avenue and Twenty-eighth Street with a rush of applicants for treatment and diagnosis. More than 250 persons were treated the first week and appointments for 750 more were made for the second week.

Charles F. Neergaard, Director of the clinic, has said that the public's response to the opening of the first "pay clinic" in this city for general medical service has been so great that it was probable that the hours will be extended to include the entire morning and up to 7:30 every evening. In the meantime, no one will be turned away. Whenever the rush is so great that all the applicants on any day cannot be treated, appointments will be made for those who failed to get consultations.

Before the clinic doors were opened on the first day, applications had been received from 350 persons wishing treatment. Appointments for these persons were made over a week's period. The policy of the clinic is to make appointments for half the number of cases which the staff could treat, leaving half of every day's clinic hours free for those who applied for medical services without previous appointment.

In line with its announced policy of "privacy, individual care and unhurried and courteous service," those in charge of the clinic had arranged the entrance hall and the offices of the staff so far as possible like the offices of private physicians. All patients were met at the door by a "hostess." Appointment patients were taken to the registrar ten minutes before the appointment hour. Patients without appointments were

Keystone View Co.
Patients waiting in line in the prescription department of the clinic

given numbers in sequence. Appointment patients were alternated with those who had no appointments.

In the registrar's office registration and history cards were issued and the patients received admission cards. These they presented to the cashier with the fee—one dollar for ordinary examination or treatment, \$2.50 for health examinations and ten dollars for special diagnoses. The histories were filed with the librarian.

The patients, on arriving at the different clinic divisions, of which there are three general and fourteen special, were met by the clinic executives and then assigned to the physicians in private offices. After examination and treatment, the physicians, whenever necessary, wrote prescriptions, which were filled by the clinic druggist at cost. Appointments for further treatment were also made directly with the physicians.

Many Physicians on Staff

Seventy-six physicians are on the "pay clinic" staff. They are members of the faculty of Cornell University Medical College, and they include many distinguished specialists. The staff is distributed among the different departments of the clinic as follows: Medical, twelve; surgery, seven; obstetrics, four; genito-urinary, ten; neurology, twelve; psychiatry, seven; dermatology, five; otology (ear diseases), four; laryngology (throat diseases), five; orthopedic surgery, four; eye diseases, including fitting of glasses, six.

About one-third of the cases treated at the clinic were in the general medical division. Almost a fourth went to the clinic for general health examinations. Of the special clinics,

the ear, nose and throat divisions and skin and eye divisions treated the largest numbers.

The present clinic hours are from 1:30 to 4 p. m. daily, either with or without appointment, and from 5 to 7:30 p. m. on Tuesdays and Fridays.

Dr. Walter N. Niles, dean of the medical college, has asked the cooperation of medical societies and physicians in this city.

"The medical profession," he said, "is offered the cooperation of a group of specialists, to which it may refer needy cases for general diagnosis or single examination. Cases so referred will be returned to the physician after careful study with a written report of findings and recommendations for treatment. No case referred to the clinic will be given treatment except at the direct request of the referring physician.

The desire to cooperate, not to compete, with the general practitioner is emphasized. The college looks to him in referring cases, to protect both the medical profession and the clinic against abuse.

The diagnostic clinic will be directed by the Department of Internal Medicine, which will analyze the reports of the specialists in connection with the laboratory findings and after consultation determine upon the diagnosis and proper treatment. The members of the college faculty will exercise direct supervision and control over the work in the clinics and will take an active part in the diagnostic procedure. Members of the profession who wish to accompany their patients will be welcomed at the clinic.

The Academy of Medicine and the County Medical Society have been asked to cooperate. All agencies are to unite to extend adequate attention to all applicants for service.

*"America's
most
famous
dessert"*

JELL-O
*is much
more than
a dainty
dish*

The institution size package represents the same standard of quality that has made our product such a favorite for so many years.

Laborers, mechanics, factory workers and shop men need Jell-O, too.

An attractive dish should be more than just attractive. Jell-O is not alone of benefit to the housewife who would have her culinary efforts appeal to the eye and palate of the guest, or to the ill whose appetites must be coaxed back to normal. Jell-O supplies in the diet what every manual worker must have to remain efficient—tissue repairing and protecting qualities to offset the fatigue and physical wane due to the day's hard grind.

Industrial production depends upon individual effort. It cannot be speeded up while the individuals responsible for it are sagging down. The worker's diet must be related, in some measure, to the effort required of him. Jell-O retards tissue waste without in the least causing the physical depression produced by the eating of heavy foods. It is very easily digested and assimilated.

Workers eat Jell-O with great relish. Served in the industrial lunchroom or cafeteria, with fruits, pastries and in many other ways, its tasty appearance goes a long way toward making the employee's meal time a period of pleasure and satisfaction.

Health Stunts to Interest Everyone*

BY LEONHARD FELIX FULD, LL.M., PH.D., NEW YORK CITY

THE sympathy which expresses itself in commiseration of the lot of men who must work overlooks the fact that ease and inactivity are not unmixed blessings, but may constitute a menace to health and well being proportionately greater than attends even strenuous living under reasonably favorable conditions. Nature very definitely demands the

This series of exercise affords a wide choice of stunts which combine features of work and play.

No. 5. *Jumping Jack*.—Are you fond of skipping rope? Are you proud of your record? How many times can you skip without missing? Are you proud of your rhythm? Proud of your balance? You have a right to be proud. Skipping rope properly

your balance. Watch your posture. Watch your rhythm. How many times without a break? Easy riding without an emergency stop. Leave your rope at home and try the Jumping Jack with your friends. Who is the best Jumping Jack?

No. 6. *Play Ball*.—Are you cross some days? Is your liver out of order? Must you rely for health and comfort on something which works while you sleep? Don't be a drag on your friends and business associates. Shiver your timbers, shake your innards, and play ball. Did you fail to bring a ball? Use your body as a ball. Sit on the ground with your feet together and your knees bent and high. Place your arms underneath your knees from the inside and clasp your hands in front of your ankles. [Fig. 7.] Start the ball rolling. Sway your body until you lie on your left thigh and your left shoulder. [Fig. 8.] The momentum will carry you on your back. [Fig. 9.] Next you will lie on your right thigh and your right shoulder. Now you are sitting again on the ground in your first position. Keep on rolling. Loosen your liver. Cheat the patent medicine man. Relieve your friends as well as yourself. Play ball. Shiver your timbers and shake your innards. Get that priceless habit of regularity. Acquire a sunny disposition even on cloudy days. Play ball. Be happy. Enjoy life.

No. 7. *Kick Up Your Heels*.—Are you a namby-pamby? Do you

Fig. 6.—This is the first position in skipping rope without a rope

Fig. 7. This is the way to start the ball rolling. It is some stunt to keep it rolling

Fig. 8.—Second position in the game with the human ball. The momentum should carry the body back

strenuous life. Continuous development characterizes only the motor types, and only under conditions involving continuous exercise are the physiologic functions maintained in proper equilibrium. The human body is conditioned to properly proportioned effort and rest. If the day's work does not impose all round muscular effort, then the daily exercise must be depended upon to supply it.

requires much skill and experience. How about that little heart of yours? How about your spine? Do they enjoy skipping rope? What happens to them each time your feet strike the ground? Do they feel as you do when the motorman on the car applies the emergency brakes? Did you ever skip rope without a rope? Try the Jumping Jack. Raise the heels and bend the knees. Go all the way down. [Fig. 6.] Straighten the knees and rise on your toes all the way up.

Down and up. Keep it up. Watch

Fig. 9.—Indulge in this exercise and cheat the medicine man

Sherman's Polyvalent Vaccines

A more adequate and rapid immunity can be established with polyvalent vaccines than from an infection itself. SHERMAN'S POLYVALENT VACCINES rapidly stimulate the metabolism and defense of the body with a resultant prompt recovery in general acute infections.

Given early, bacterial vaccines almost invariably cut short the common pyogenic infections of the skin, mucosa joints and tissues;

Administered in advanced cases, they usually ameliorate or abbreviate the course of the disease;

Even when used as a last desperate expedient, they often reverse unfavorable prognosis.

The immunizing powers of stock vaccines are demonstrated by the prophylactic efficiency of typhoid vaccine. Bacterins made from selected, vigorous organisms are far higher immuno-producers than autovaccines prepared from feeble, degenerated organisms sometimes found in the patient's own specimens. Especially in acute cases, the PROMPT injection of a stock bacterin is decidedly preferable to the DELAYED injection of an autogenous one. The place for autovaccines is in chronic infections which fail to clear up under stock bacterins due to the prob-

able presence of some unusual bacterium.

Advanced inflammatory processes due to only one class of bacteria are rare, mixed infections being the rule. Therefore, COMBINED VACCINES, containing all strains likely to be present, give the best assurances of success; an unneeded variety of the bacterin is harmless and in no way weakens therapeutic response.

Thus the favorite invaders of the nose and throat are the pneumococcus, the streptococcus, the staphylococcus and the micrococcus catarrhalis, calling for Sherman's No. 40, and in chronic cases—when there is a foul odor produced by the Friedlander bacillus—Sherman's No. 36. In visceral infections, due chiefly to the colon bacillus with the pus cocci, Sherman's No. 35 is appropriate. In Neisser infections, if these organisms are not already allied with the gonococcus, the imminence of their entrance is so great that the rational combination is Sherman's No. 49.

When, particularly in grave cases, valuable time may be lost in securing the variety of vaccine especially recommended, it is always advisable to use the vaccine at hand which contains the predominant organism of the disease to be combatted.

Sherman's 10 Mil Container

This package has many superior features which assure asepsis, prevent leakage and facilitate the removal of contents. It is constructed on the well known Sherman principle.

The vial is amply strong which prevents breakage so frequent with shell vials.

We are exclusive and pioneer producers of Bacterial Vaccines. Originators of the aseptic bulk package. Pioneer in elucidation, experimentation and clinical demonstration.

Twenty Preparations.

Beyond the experimental stage.

**BACTERIOLOGICAL LABORATORIES OF
G. H. SHERMAN, M. D.
DETROIT, U. S. A.**

"DAILY USERS OF VACCINES USE SHERMAN'S"

Fig. 10.—The somersault is a simple and easy performance that carries its own reward

Fig. 11.—Position two of "Kick Up Your Heels," which is simple enough if you are not afraid of exertion.

always keep your heels on the ground? Don't you ever dare to cross your knees? You will get your reward in another world while your friends continue to enjoy themselves in this. Namby-pambies get this reward sooner than they expect. They are generally sickly. Namby-pambies seldom amount to anything. The worth-while man or woman needs a strong mind in a strong body. Be a regular boy. Be a live girl. Kick up your heels. Put your hands on the floor and place your head on the floor between your hands. [Fig. 10.] Turn a somersault. Kick your heels over your head to the other side of your hands and lie flat on your back. [Fig. 11.] Rise to a sitting position. Grasp your ankles and stand up. [Fig. 12.] Keep your head when everything is upside down. Shake your innards and get that priceless habit of regularity free of charge. Be a complete master of yourself at all times and you will soon control others. Don't be a namby-pamby with your heels on the ground. Be a regular fellow and kick up your heels.

No. 8. *The Crane Walk.*—Have you been practising the yellow dog? Can you do the dog trot? [Fig. 13.] Have you noticed how this trot is developing your pipstern arms? How your rhythmic deep breathing is filling out the hollows of your chest? It is fun, too, is it not? Who can dog trot fastest? Who farthest? Who

most like a dog? Do you dog trot from your bedroom to your bathroom every morning? If you can dog trot with facility begin to crane walk. You know the crane—that long-legged,

Fig. 14.—Bend forward at hips till hands touch the floor to develop muscles you are neglecting.

stiff-kneed, haughty creature? With knees stiff and unbent, bend forward at the hips until the hands touch the floor. [Fig. 14.] Walk in this position. You will quickly dissolve any surplus fat on your abdomen. You will rapidly acquire that priceless habit of regularity. You will develop parts of your legs which you have neglected before. Don't be satisfied with envying a shapely body. Crane

walk and acquire one. Nervous and physiological equilibrium is an achievement, not a gift. Not alone should the hours of leisure be spent in pursuits which call forth different thoughts and feelings from those suggested by our daily work, but supplementary exercise should be constructive and corrective.

Comparison of Intelligence Tests

Comparison recently was made by Luella W. Pressey in the *Journal of Applied Psychology* between "A" country and city children and "B" children from different economic levels, by means of a group scale of intelligence applicable to the first three grades. It was found that 22 per cent of the country children six to eight years old score above the median for their age made by city children. Children of profession and business men rate distinctly above the children of laboring men and mechanics. Similar results were found in surveys by means of scales applicable to the older children. It is, therefore, argued that the differences previously found were differences in innate ability, not in schooling or home culture, and that there was some general factor, presumably general mental endowment, independent of the particular tests used, with respect to which these groups differed.

Fig. 12.—Stand up, still grasping the ankles. Keep your head with everything upside down.

Fig. 13.—This will serve to develop the arms and promote rhythmic deep breathing

How the Right Shoes Increased Her Sales

A true story with a lesson for all men and women

"MISS GREEN, you and eight other girls out of seven hundred have shown increased sales during the last three months. All the others show losses. Why have you been able to increase your sales?"

"Who are the eight girls?" asked the young woman

The president of the store read the names. The girl seemed happy to answer:

"Shoes—Cantilever Shoes. I got them first. Later I took each of those girls, in turn, to the Cantilever Shop. In Cantilevers, you see, our minds are off our feet. The business gets all our attention. We don't feel cross, cranky or tired. I suppose that's why our sales are good."

That afternoon the president of the big store walked into the Cantilever Shop and asked a salesman to explain the features of Cantilever Shoes.

The Cantilever salesman took a shoe and bent the sole at the shank, showing how the shoe

conforms to the human foot, even to having a flexible arch like the foot. He said, "The arch of the foot should flex with every step, according to nature, yet ordinary shoes are made rigid by a concealed metal shank-piece that forbids free movement of the muscles. There is no rigid shank in Cantilevers. The 'waist' is designed to hug the instep, the shoe fits and supports the arch restfully. The flexibility allows the arch muscles free play and this, together with the natural lines of the shoe, permits perfect circulation.

"It is important to allow the foot muscles to exercise, to keep well and strong. The forepart of a Cantilever Shoe is shaped to look well, while allowing the toes to lie in their normal position. Cantilever heels are moderately high—high enough to be smart, without throwing the posture of the body out of balance as exaggerated heels do, causing unnatural pressure and strain on the nerves and the internal organs. By wearing Cantilever Shoes a woman avoids headaches and backaches, irritability and nervousness. She is brighter and happier."

"The subject is of great importance to the business woman who is required to stand during the greater part of the working period. The tired feeling often complained of at the end of the day's work may be attributed to ill-fitting shoes."

Dr. Wilmer Krusen, head of the Department of Public Health of Philadelphia.

"Pain is a great foe to good looks. Comfort works just the other way. If you are comfortable, you are apt to be pleasant, and pleasantness and prettiness are often synonymous terms. Eliminate as many of your worries as you conveniently can, and your tight shoes."

—Grace Margaret Gould on "Good Looks" in Woman's Home Companion.

"Working women are the worst offenders. It is the girls who are on their feet most who persist in wearing the highest heels. Sensible women have learned that they can increase their efficiency and even earn bigger salaries by wearing shoes built for solid comfort and health."

—Dr. Evangeline W. Young, of Boston.

If no dealer listed at the right is near you, the Manufacturers, MORSE & BURT CO., No. 1 Carlton Avenue, Brooklyn, N. Y., will mail you the Cantilever Shoe Booklet and the address of a nearby dealer.

A Shipyard Cafeteria

GOOD food, cleanliness and quick service is the guiding principle of the cafeteria for employees at Morse Dry Dock & Repair Company, Brooklyn, N. Y., a ship repair yard with four thousand workmen.

An inferior grade of meat or produce will positively not be accepted by the manager, regardless of the difference in price, and it is clearly apparent by the attitude of the patrons as well as their direct expressions of appreciation that they recognize the care in selection. A first-class chef

Light and cleanliness mark the dining room appointments of the Morse Dry Dock & Repair Company, Brooklyn, N. Y. Men who bring their own lunches eat here, supplementing the box lunch with a cup of coffee and perhaps a bowl of soup.

further assures that the food is properly cooked.

Quarters Are Attractive

The air of cleanliness is distinctly noticeable in every department of the service. Though the workmen and their clothes are usually far from clean, due to the nature of their work, the room which they enter for their noon lunch is spotless from the clean whitewashed walls to the glistening white oilcloth-topped tables. The kitchen, dishes and serving likewise counterpart that of a well kept home.

All this would be of little effect, however, were it not for the facilities for quick service, for this type of workmen is without doubt impatient of delay at this time. Two runways are provided with two waitresses at each to keep a supply of full plates ready for the men in passing. A checker at the outlet of the two runways places on each tray a check punched for the proper price. Actual practice shows that 250 men can be easily and effectively cared for in twenty minutes.

The spirit of the establishment is service, urging the men in the yard who bring their own lunches to feel free to eat them in this dining room, buying simply coffee, desert, or noth-

ing at all. The prices are low, making possible a light lunch for a quarter or less and a big meal for half a dollar.

While the cafeteria is conducted as a private enterprise under the direction of two women employed in other departments of the Morse Company, it is not designed as a money-making proposition, their desire being service and making both ends meet with a slight margin of profit if possible.

This enterprise fulfills a distinct need, for while many men, now as before its establishment, bring their own lunches or patronize the restaurants of the type to be found in an industrial section, many prefer a dining room distinctly for Morse men where they can be sure of good food, well cooked and at a moderate price. This need has been excellently provided for by the yard cafeteria.

In connection with the cafeteria proper is a separate room where men who so desire are waited upon at tables seating four to six men. Here, of course, the service is not so quick and it is patronized more by foremen and office workers. However, the food is just the same and all are welcome here as in the main cafeteria.

Menus consist of soup, a plate of hot meat, potatoes and vegetables, tea, coffee, and milk, home made pies, puddings and ice cream. During the summer, salads and various kinds of sandwiches are popular for a light noon lunch.

The cafeteria is conducted as a private enterprise, under the direction of two women employed in other departments of the Company. However, service is emphasized rather than excessive profits, and the foods are closely adapted to the workers' tastes and needs.

All in all, it is believed that the cafeteria service for the Morse workmen is effective and appreciated by those it serves, and adds to the morale of the employees.

Investigations that have been made in working class homes have shown very definite relationship between the amount and kind of food and the work done. In practically every case the consumption of proteids has been proportionately high. Some nutritionists hold that this is necessary. On the whole, where food consumption has been studied in relation to occupation the consumption of proteids has been singularly low, and it is to be regarded as significant that it is highest in the heaviest trades and in the highest paid occupations, which may or may not be an unconscious effort on the part of the workman to adapt his diet to his particular requirements.

From the viewpoint of scientific needs the general conclusion of practically all these studies has been that the food of the workman generally is not well chosen for physiological purposes. Certainly more precise studies as to the energy expenditures in different trades make possible the improvement in food hygiene so as to provide workmen with a ration calculated to enable him to do his work and still maintain the necessary reserves. These principles can well be applied in the company lunch room and will be appreciated by the men. In practice it is found to be true economy as well as true humanitarianism to look closely into the welfare of the workman in this regard.

Metatarsalgia and Callouses Caused by Weakened Transverse Arch

This condition is recognized by depression of the Transverse Arch anteriorly or at the base of the Metatarsal bones. The dome-like arching is obliterated and painful callosities or corns form over the depressed Metatarsal heads. The foot broadens, the toes become dorsal flexed. Bunions appear at the First and Fifth Metatarso-Phalangeal articulations. Digital nerves become impinged and severe cramp-like pains are experienced through the toes. This is described by Whitman as Morton's Toe.

These conditions, Doctor, are quickly relieved and permanently corrected by the use of

Dr Scholl's *Corrective Foot Appliances*

These appliances are especially designed and constructed to restore the Anterior Arch, remove abnormal pressure and permit full freedom of motion to the entire foot. Different types to meet all emergencies.

Sold and fitted by leading shoe dealers in

every community who have been instructed in Anatomy of the foot and how to properly apply correctives to the foot and shoe.

Important pamphlet, "*Foot Weakness and Correction for the Physician*," mailed upon request.

NEW YORK TORONTO LONDON

Dependence and Disease

BY S. P. MOORE, CHICAGO

THE medical sciences have advanced prodigiously in recent years by means of highly perfected instruments of precision which have extended the bounds of observation and enabled a wider comparison of disease conditions. Elaboration of method along with refinement of technique has tended virtually to reduce diagnosis to the mathematical demonstrations of the physical laboratory.

Some reaction has come, however, from the increasing absorption of the pathological laboratory with the end results of disease, while cure, if it is to affect either mortality rates or disease incidence, must come from recognition and interference in early stages before the disorder has made serious inroads upon the organism. At least one school of medical thought, headed by Mackenzie, has elected to study the incipency of disease rather than its remote effects and so to correlate the clinical signs as to detect and prevent disease rather than by research to illuminate only its final chapters. Along with this is the tendency to take into account both individual and racial resistance.

Authorities differ even in the definitions of disease, what it is held to be depending largely upon the point of view. J. Arthur Thomson, declares in "The System of Animate Nature" that disease in nature is a contradiction in terms; that, apart from parasites and senescence, there is almost no disease in wild nature; should a pathological variation arise, it is eliminated before it takes grip. Thomson goes on to define disease as "the occurrence of a metabolism out of place, out of time, out of tune, and says that Nature makes short work of such idiosyncrasies. He discusses interestingly the relations of commensalism and symbiosis which, when not kept within limits, lead to a parasitism destructive of the host; but even this he regards as a sifting out which ultimately makes for racial health.

Background of Disease

Many medical men are laying increasing emphasis upon the need for the social and even hereditary background in the diagnosis and treatment of disease. It is well understood that races at the summit of their vitality can resist and fully survive epidemic attacks of protoplasmic disease which would hurry a declining stock to its extinction, as is too well

exemplified in the declining races of the South Seas. There is also to be considered the dire consequence of the introduction of the parasite into a new area, where it finds new hosts abnormally susceptible to it. The fatality of a new microbe introduced into a new population is familiar, as in the case of the Black Death in England.

The effect of the parasite on the host is extraordinarily varied, some giving off toxic substances; others causing lesions and inflammations; some promoting growths, while some do very little harm. The biologic chemist needs often to be called upon to trace these effects, but this pathology is only one phase of the subject. Biology, too, has contributed to the understanding of disease. The organs which are the latest product of evolution are usually the most prone to disorders of function, and the three levels in the evolution of the nervous system underly the grouping of certain disorders. It is rather a newer idea to search geologic records for evidences of typical degenerations of anatomy and function.

Several paleontologists have contributed to the subject of disease in their studies of the universality of parasitism, and the inference that pathologic parasitism has continued for vast ages. The most recent contribution to this subject is the book on "Organic Dependence and Disease," by John M. Clarke, New York State Paleontologist. He makes a study of the metazoan parasite and attempts in the clear evidences in geologic records to find the inception of abnormal physiology in nature. Pathologic conditions, or disease, he holds to be as much a product of evolution as the human hand or the bird's wing. Clarke calls whole races diseased if they have departed from what was for them normal living, and finds in geologic specimens of early, undifferentiated types the clues to the beginnings of disease.

Disease he defines as any departure from normal living. Normal living, biologically, is progressive living, mobile living, independent living. Dependent life, therefore, becomes a perturbation of function. Progress has ever attached to the motor types. The knell of progress is struck for a type when it settles down to a fixed, immobile existence; while in the mobile types, very low down in the

scale there occur the beginnings of purposive activity which in their developed forms can be interpreted only in terms of psychology.

The early partnerships of organisms were of mutual helpfulness, whatever their risk to progress. Acquired habits of dependence, however, led to modifications in both parasite and host. The conclusion must be reached that microbic disease is an abnormal adjustment, satisfactory for the invading organism but obnoxious to the host. For dependent species there is no hope. "Those who have not yet fully learned their subjection to Nature's laws, are engrossed with the passing interpretations of social problems, with expediences of the statute; and the cares of the world; to these should go the assurance that in greater measure than they may have suspected the clue to human destiny lies concealed in the rocks beneath our feet." Through such prehistoric record is to be attained a better perspective of the incipency of disease. The bearing of ethnology on psychology thus finds its parallel in the illumination of the subject of disease through paleontology.

Closely related to this subject is an article in a recent issue of the *Scientific Monthly*, under the title "The Biology of Death—Natural Death Public Health, and the Population Problem," by Professor Raymond Pearl, who declares that the duration of life is an inherited character of an individual, that the breaking down of an organism preceding death is not a haphazard process, but an ordered sequence, cellular death likewise growing out of inter-cellular dependence. The problem of disease is not wholly one of infection, and the "potential immortality" of the essential and important somatic cells of the body affords possibilities of better individual and racial resistance than is generally conceded.

He makes interesting observations on the promptness with which a population tends to regulate itself back toward the normal even after the disturbing upset of a war or wholesale epidemics, and calls attention to the fallacious reasoning of propagandists who claim undue credit for reduction in certain mortality rates inasmuch as the death rates from non-controlled causes of death have shown the same steady decline during the past nineteen years as has marked the controllable causes of death.

Well conceived and careful studies are called for in the elucidation of the most promising fields of public health activity, and he regards studies of

The value of yeast in the treatment of acne

"THE causes of acne are always found in a lowered vitality, very commonly associated with constipation and metabolic disorders," writes a physician connected with several large New York hospitals. According to statistics of this same physician constipation is present in about 45 per cent of acne cases, according to another physician in about 35 per cent.

A number of well-known physicians and physiological chemists have given bakers' yeast a careful test as a therapeutic agent. (See *Journal of the A. M. A.*, Vol. LXIX, No. 15.) In 25 cases of the acnes (17 acne vulgaris and 8 acne rosacea) yeast proved to have properties of great value in remedying the basic causes of this complaint.

Every case showed improvement or cure. The acne vulgaris cases required from one week to two months, the acne rosacea from a few days to four weeks. Typical of the acne vulgaris was the case of a young man who had a moderate eruption on face and body during three years. Three cakes of yeast daily before meals for five weeks was the treatment prescribed. The eruption cleared almost completely in four weeks.

The laxative action of yeast was proved both in correcting constipation itself and as a result of feeding experiments on normal persons. In regard to these acne cases Dr. Hawk states: "Whether the success of yeast in acne vulgaris and acne rosacea is due alone to its laxative action or to some fixed effect on the intestinal tract we are unable to say. The preparation was laxative in all these cases."

Nutrition experiments carried on at Jefferson Medical College both with rats and with men demonstrated the value of yeast in stimulating metabolism. Thus both clinical observation and laboratory research have clearly indicated that yeast helps correct the basic causes of acne.

In the tests referred to Fleischmann's Yeast was used, as that is the best known and most widely used of ordinary bakers' yeast.

Fleischmann's Compressed Yeast may be secured fresh, daily, from grocers. If the physician prefers he may write to The Fleischmann Company in the nearest large city and it will be mailed direct on the days wanted.

Usual dosage: One cake of yeast, t.i.d., before or after meals, plain or in a suspension of water, fruit-juices or milk.

THE FLEISCHMANN COMPANY, 701 Washington Street, New York, N. Y.

occupational mortality as especially likely to yield large returns. The highest credit for improvement in health conditions is due to the health activities dealing, of necessity, only with environmental matters. "Of all activities looking towards the modification of the environment to the benefit of mankind, that group comprised under the terms sanitation, hygiene, and public health have by all odds the best case. . . . When based upon a sound basis of ascertained fact it may, and does, proceed with a step as firm and inexorable as that of Fate itself, to the wiping out of preventable mortality. . . . Some of the work, however, has no such foundation, but is built upon the exceedingly shifty sands of ignorance. . . . We shall save a good deal of money and human energy, if we first take the trouble to prove that what we are undertaking to do is in any degree likely to achieve any useful end."

Yale University Press, 1921.

Relation of Medicine to Industry

A meeting was held in the offices of the Industrial Welfare Society in London, June 2, at the same time that a series of conferences were being held at the Guild Hall under arrangements made by the Royal Institute of Public Health, the subject under discussion being industrial medicine. The Duke of York in opening the proceedings used the following words, "Industry has been too long carried on without thought of its effect on the worker."

The conference was of a strictly practical character, being concerned with what should be done to maintain and improve the health of the workers, and what steps ought to be taken to make the resulting advantages of healthy labor quite clear to the minds of the employers. It is evident from the discussion and reports that there is a great need of arrangement and coordination, of the establishment of new activities, and the planning of programs without interference from the old established customs or interests. The problem of prevention through timely examination, the establishment of dental clinics, the provision of trusses, the shortening of disablement period after accidents by electrotherapy and massage, clinics at the workplaces, provision of half-time or light work for convalescents, removal of men from dangerous work at an age when slight accidents might make them permanent cripples, are

examples of the care of the individual worker already in evidence.

Much remains to be done toward making unhealthy processes healthy and removing the causes of long-standing ills. Industrial phthisis presents huge difficulties.

The presence of the doctor in the works, on the Whitley Councils, and on the Work Committee does much toward solving the problem of his own position and making him a part of the general system. Conversely, the average medical practitioner has not studied at close range the problems of the employee and employer, in spite of his real desire to aid and abet sound therapeutics. Any attempt to upset the management of industrial concerns by ill-considered, bad features, founded on inadequate knowledge brings the entire movement into discredit. Whatever the exact method adopted, the works doctor must be in close touch with the general practitioner as well as with certifying factory surgeons.

Industrial medicine must not be under "close" specialism and if the general practitioner is to acquire a preventive outlook he must have the opportunity to study the effect on his patient of both the home and occupational conditions. Home conditions

must be right and, manifestly, and men fitted to their jobs. Intelligent medical supervision takes account of both conditions. Once inaugurated on safe and sound lines, industrial medicine is likely to go ahead faster than some may think, according to the review in *The Lancet* of June 11, 1921.

Cares for Children in Cotton Mill Districts

That North Carolina is prosecuting still further her survey into the sociological aspects affecting the health and welfare of her people is evidenced by the welfare work in cotton mill communities, as reported in the April, 1921, issue of the *Southern Textile Bulletin*. Recreational needs are being taken care of at Draper, a typical community, by the Welfare Department of the Carolina Cotton and Woolen Mills Company and the Y. M. C. A. A large and well equipped playground has been opened for the children. A class of sixty men and boys, ranging in age from fourteen to sixty years old, was recently graduated from the vocational training night classes of the mill communities of Leaksville, Spray, and Draper.

Plan to Combat Tuberculosis

THE report of the Committee on Tuberculosis to the Supreme Council of Knights of Columbus was an effective document as an offensive agent against the disease and resulted in that Organization committing itself to a continuous campaign involving:

(1) A general educational campaign among the members of the Organization as to the cause and prevention of tuberculosis. The object of this campaign is to convince the various councils of the Order that they should take up tuberculosis work and do all that is possible to prevent tuberculosis among the families of their members; to discover and care for existing cases. Schools are to be interested in the Modern Health Crusade as a system of health education suitable for children of school age, its purpose being to form good health habits, to promote community service, and to arouse a sense of responsibility for the control of preventable disease.

(2) The care of children is to be emphasized, inasmuch as it is now generally recognized that the period of infection from tuberculosis is

chiefly in the childhood years. School nurses are to be employed and children's clinics established. By these means incipient or suspected cases of tuberculosis are discovered early and provided for either in open air schools, summer camps, and, when necessary, by care in sanatoriums or children's institutions.

(3) Local dispensaries and clinics are to be provided for the care of adults. These will provide opportunity for complete physical examinations as the best possible health safeguard.

(4) After-care is to safeguard the patients pronounced as arrested or quiescent. Convalescent provision, vocational counsel, and visiting nursing service will constitute the machinery of this important phase of the work.

The Committee responsible for the comprehensive study of the situation and for its able statement in the report quoted are: Jame L. O'Toole, Pennsylvania, chairman; Drs. E. W. Buckley, John F. O'Briend (Massachusetts), Stephen J. Maher (Connecticut), and Mr. Thomas A. Lawler (Michigan).

Nurses Lightweight Portable Scale

for Weighing and Measuring Babies, Children or Adults at Rural Schools, Welfare Stations and General Field Service

Can you imagine a handier equipment than a scale **LIGHT ENOUGH** for you to handle in transportation, yet possessing every worth-while scale feature. You can set the Continental scale up in less than two minutes. There is no lighter scale made, yet none is more efficient.

CONTINENTAL Nurses Lightweight Portable Scales

are designed and built to serve the rigid requirements of traveling nurses. Every Continental scale is designed for a given purpose and meets it thoroughly and efficiently. Continental Scales are accepted everywhere, for professional use—and there's a reason!

Learn more about the Continental Nurses Lightweight Portable Scale. The "Continental Seal of Accuracy" is your quality protection and guarantee.

Literature on the Continental Nurses Lightweight Portable Scale is yours for the asking. Write for it today.

CONTINENTAL SCALE WORKS

2122 West 21st Place, Chicago, Ill.

72 Murray Street, New York City

Model No. 526
Capacity 210 lbs.
Graduated in Ounces.

With carrying case, ready for any method of transportation.

When A Baby Must Be Weaned

there is no food that can be used to replace its mother's milk, with greater convenience and benefit, or less trouble and danger, than

Nestlé's Milk Food

Made from pure cows' milk, malt, cane sugar and wheaten biscuit, Nestlé's Milk Food enables the painstaking physician to provide the infants under his care with a digestible and nourishing food that assures every advantage of properly modified milk, with gratifying avoidance of inconvenience or danger.

There is a constantly increasing number of physicians, therefore, who are finding in Nestlé's Milk Food, not only modified milk at its best, but a food that means "in weaning the baby," a new era of improved health and progressive bodily growth.

Health of Detroit School Children

SCHOOL medical inspection is intended to remove the tragedy of unnecessary handicaps induced by preventable disease in early childhood. Prominent among the crippling conditions of early development is undernourishment, its most serious aspect being that it is attended by a corresponding lowering of the vitality which renders the child an easy victim of disease. Amar warns that inanition is particularly to be avoided in children, their development suffering from it. Even if followed by abundant nourishment, the normal development of the muscles is affected.

During the past year the Board of Health of Detroit has sought to determine the number of malnourished children in the public schools. From analysis of 58,581 records, it was found that 11,368 were ten per cent or more under weight, and of these 3,943 were 15 per cent or more under weight. The school attended by white—Canadian, English, and Scotch ancestry—were found to show the greatest percentage of children under weight; while the schools attended chiefly by children of Russian, German, and Polish ancestry were found to have the smallest percentage under weight. The comment of Dr. L. O. Geib, supervisor of Medical Inspection, in this connection of the advantage of the children of foreign extraction in receiving principally the more common foods, high in caloric value, instead of the sweets and pastries so popular with the average American child, is significant.

A résumé of the work of the findings of the investigating committees in Detroit is fully set forth in the August-September issue of City Health. Their preliminary study of standards of growth as applicable to Detroit Schools are as follows:

(1) Weight and height bear a very definite relationship to school progress.

(a) Retarded children are generally shorter and lighter than children in grade at age.

(b) Accelerated children are generally taller and heavier than children in grade at age.

(2) Nationality must be considered as an important factor in any final growth table.

(3) Boys grow faster than girls up to 10½ years.

(4) Girls grow faster than boys

from 10½ years to approximately 15 years.

(5) An intensive study of individual types of relation to ratios should be made to determine the exact value of the ratio table.

(6) Height and weight measurements can be made accurately by teachers for practical purposes.

(7) Children should be measured at least three times each year: (1) at the beginning of the first semester; (2) at the end of the first semester, and (3) at the end of the second semester.

(8) A study of height and weight of all children in Detroit Public Schools should be made in 1921-22 to develop a complete growth table for Detroit.

(9) The history of the child regarding illness and physical defects must be given careful consideration

in relation to his height and weight.

(10) It is probable that a careful study of the height and weight of the parents might throw light upon the reason for the variations of the children.

(11) The tremendous variation within an age group suggests that height and weight are determined by a large number of factors other than age and sex so that interpretation must be based upon a series of laws rather than a single law.

(12) Study should be made at once of the physical defects of a sufficiently large number of children in each age group to determine the relationship each of these defects bear to the general health and progress of children in the public schools. The figures compiled from studies of special groups are highly important and especially are the figures from Detroit valuable, as they may be considered to represent a typical urban group.

TABLE I—WEIGHT-HEIGHT RATIO OF DETROIT BOYS

4 MONTHS' RESULTS

A Springfield (Mass.) woman suffered from flat feet and bunions caused by wearing narrow-toed shoes. A local doctor advised her to wear

GROUND GRIPPER WALKING SHOES

She did, and he kept careful diagrams of her feet from April 19th to July 10th. The above drawings are reproduced from his records. They speak for themselves.

"GROUND GRIPPERS" are the ORIGINAL muscle-developing health shoes for Men, Women and Children. They are universally recommended by physicians and surgeons. Instead of imprisoning arches and toes, they flex naturally with your feet in every part—at every step. Nerve pressure is relieved—stagnant circulation quickened—weak muscles strengthened—painful swellings reduced—deformed bones straightened. Feet are completely restored to normal shape, vigor and comfort. And these results are permanent.

"GROUND GRIPPERS" are imitated but never duplicated

Health Notes Now Valued As "News"

An able medical writer in the *London Times* is writing a series of illuminative articles on problems relating to individual and public health. The degree of disease tolerated by a community, he says, represents the measure of attention centered upon health problems. Of incalculable benefit, either to individual or community, is the determination to live, the purpose which seeks rational methods of putting unfitness away and developing to the utmost physical resistance. He warns against obsession by symptoms, but declares for rigorous activity and wholesome ways of living.

Another of his significant messages is directed toward habitual drug users—not the victims of narcotic drug addiction, but that large number of men and women who take day after day salts or vegetable astringents, or metallic compounds with the mistaken notion that they stimulate the digestive tract. These irritants set up a kind of inflammation of the mucous membrane of the intestine until presently, the whole digestive tract, a delicately adjusted and automatic mechanism, refuses to be whipped any longer. Drugs should be avoided as much as possible in certain conditions, but this sort of self-medication and amateur doctoring takes no thought of the limitations of drugs or the special needs in a given condition.

A failure in function represents some failure in the art of living, declares this author, and demands that a man examine his way of life in order to discover where it falls short of efficiency. Above all, he should avoid bombarding his system with medicines; otherwise, he will find himself increasingly unresponsive to drugs, and will enter "that miserable company of people who are ever on the lookout for new medicines."

The Factors in Proper Physical Development

The broadest need of the people, whether on peace or war time basis, is such measures as will make men physically fit to withstand active service. Fundamental to such a state of physical development must be an exact knowledge of the mechanics of the body.

The ideal posture to be developed is the natural standing position, with the head erect, chin drawn in, the chest held high, the abdomen drawn

in or held flat, and the weight borne largely upon the anterior parts of the feet, in which position all the muscles are in balance, no strain is on the ligaments, nor can the viscera sag so that their function is interfered with.

The August issue of the *Military Surgeon* carries the comment by Dr. Joel E. Goldthwait on causes and correctives of the more common disability conditions in civil as well as army life. Flat feet and lame backs are for the most part due to the habit of standing so that the muscles of the feet and trunk are out of balance. Once the posture is corrected, local strains are removed, the symptoms disappear, and the general vigor is greater.

A further advantage is that as the habit of correct standing posture is formed, the diaphragm is necessarily so held that it is able to perform its part in the respiration and circulation normally. Dr. Goldthwait makes the significant observation that the erect position in which the dia-

phragm could work normally was not in a single instance associated with disturbed heart action.

Dental Hygiene Costs in Bridgeport

Dental hygiene work in the public schools of Bridgeport, Conn., costs forty thousand dollars a year, which is about \$1.50 per pupil. The saving in reeducation by elimination of absences formerly caused by "sick teeth" and by the improvement in general health, almost replaces this outlay. Educational and preventive work are emphasized rather than "repair work," the dental corps consisting of twenty-six hygienists and three dentists. Health has been made a requisite for promotion in the schools. It is expected this year to send practically all of the children from the fifth grade into the sixth with no cavities in the permanent teeth, and with all physical defects of the eye, ear, nose, throat, and skin either corrected or in process of correction.

Organic Basis of the Neuroses

OBJECTIVE methods devised for the study of neuroses by Dr. F. L. Golla, physician to St. George's Hospital, London, should bring to the greatly overworked term "neurosis" a more precise definition, and to the nervous patient whose disorders have been generally ascribed to purely psychogenic origin will hereafter be extended the diagnostic resources of the physiological laboratory. In the Croonian lectures published in the recent issues of the *Lancet*, Dr. Golla approaches the subject of mental disorder from a purely physiological standpoint. He determines the feeling tone and measures bodily response to cerebral activity in terms of the galvanic reflex. As the galvanic reflex is entirely beyond the volitional control of the patient, it becomes an exact index of the degree of organic disturbance. While the psycho-analytical method has evolved much valuable information in the realm of psychology, its therapy must be considered merely as symptomatic treatment in view of the abundance of evidence adduced by Golla in proof of the existence of organic disequilibrium in the neuroses. The exact nature of the pathology involved is still in question but microchemical changes in the nerve cells with possibly defective oxidation processes is the probable

basis of nervous asthenia. Another group of these cases shows hyperexcitability of the emotions associated with a very active thyroid, an increased basal metabolism and an irritable sympathetic system. Another distinctive type of neurosis is characterized by the manifestation of primitive instincts, ill adapted to the environment, but here as in the less obscure cases there exists a demonstrable organic imbalance, causing the disturbance of the affective mechanism.

The hysterical type, as revealed by the galvanic test, is associated with subnormal activity of the affective mechanism. The whole study of the Golla marks a distinct advance toward placing mental diseases upon an organic basis. Golla proposes the precise methods of investigation and the rigidity of objective signs to offset the undue attention which is at present devoted by psychologic enthusiasts to the classification and tracing of psychogenic origin in nervous troubles. It relieves the whole subject of metaphysical implications and clears the way for a scientific understanding of mental disorders. It affords a very definite means of diagnosis in many cases indefinitely characterized as offering problems in conduct merely, or as exhibiting propensities for malingering.

The Dermatological Research Laboratories were first in the United States to produce Arsphenamine.—Due to the systematic efforts of our research staff, with laboratory facilities and personnel adapted to intensive concentration largely in this particular field, we are now producing a NEO ARSPHENAMINE of such **low toxicity** and **high therapeutic effect** that it may be regarded as a super neo arsphenamine.

For the convenience of physicians who have not ready access to reliably distilled sterile water, we supply a bulk package (illustrated) containing 10 ampoules of any one dosage of neo arsphenamine with 10 ampoules of chemically pure sterile water, free from organic matter. Dilution may be accomplished in the ampoule and syringe.

Hospital in High School

THE schools have been earlier than health workers in taking home the lesson that we learn to do by doing. Home economics departments have employed model apartments, completely fitted up, the care of which has been assigned as a part of the routine requirements in given courses. Domestic science departments have conducted dining rooms in which actual experience in budget making, buying, handling, storing, and serving foods has been afforded to students in training. The work of these departments has contributed materially toward nutritional programs in schools, and toward dietary instruction to the pupils in general. Objective methods are the order of the day.

A recent report has it that some schools are installing student dormitories, scientifically managed under student personnel, which is a distinct advantage in affording facilities for the satisfactory housing and care of non-resident pupils.

Rochester, N. Y., has recently made the progressive announcement that a small hospital is being installed in the girl's wing of East High School. Mrs. Grace Dowdle, a graduate nurse, has been installed in charge and will attend to all cases of illness that may arise among the members of the student body during school hours. This project is being carried out by the Health Bureau, working in conjunction with the Board of Education.

Albert H. Wilcox, principal of the school, welcomed the action of the health officials in installing the nurse and approves the plan, which already has been carried out in the grade schools of the city, though under the direction of the Public Health Nursing Association.

Occupies Small Space

The miniature hospital occupies a small space. At present there is only one cot in the room, but it is planned to increase this number to three. A screen is provided for each bed. The cots will be of the folding variety so that they can be stored away when not in use.

A supply of medicine and other necessities is kept on hand. It is not known what arrangements will be made for the caring of the students' teeth, but the medicine chest will be supplied with materials to cope with toothache. Headaches, the most common ailment, also will be treated.

Besides having her roll-top desk in which to keep her records, the nurse in charge will be provided with a large filing cabinet in which she will keep a record of all cases, with a description of the entire course of each case. Plumbers are running pipes into the room so as to make available a supply of running hot and cold water.

May Feign Sickness

One branch of work to be carried on by Mrs. Dowdle will be that of supervising the issuing of leaves of absence on account of illness. Pupils desiring to play hockey have been known to begin suffering from a headache or a toothache. The nurse

will endeavor in every instance to arrive at all the facts in the case and, unless sufficient evidence is given that the patient is really suffering, she has been empowered to recommend that such requests for absence be refused.

Will Give Health Talks

The nurse will give a series of health talks through the year and instruct the students in methods of administering first aid. During the winter months there is generally little to be done, with the exception of occasional cases which might result from injuries sustained in the gymnasium. In the spring and fall it is no uncommon thing for pupils of both sexes to faint. This work heretofore has rested upon Miss A. Weyman, physical director for girls, and James Fowle, physical director for boys.

Reporting Physical Defects

OWING to the wide variations in the reported prevalence of physical defects among school children, George T. Palmer, D.P.H., epidemiologist of the Health Department of Detroit, Mich., has devised a uniform language for the use of inspectors in reporting defects. The need of this code was brought out by the fact that while 30 per cent of tonsillar defects were reported from one school, only 5 per cent were reported in a school a few blocks away. The differences were due, not to the children but to the interpretations of two medical inspectors. In an effort to secure uniformity in reporting and thus make records from different schools comparable, physical examiners now travel in teams of three men each. They come together at intervals to check it over by independently examining the same group of children. All must report defects in terms of the following graded scales:

An "X" after a numeral is the signal for the sending home of a recommendation slip to parents. The nurse follows up all "X" cases to secure corrections.

(1) *Thyroid*.—0—Normal; 1—Slightly enlarged, evident on close examination but hardly noticeable; 2X—Moderately enlarged—unmistakable enlargement and yet not markedly disfiguring; 3X—Greatly enlarged—very evident and disfiguring enlargement.

(2) *Vision*.—00—Vision corrected, wearing glasses; 0—Normal; 1—15/20 (or 20/30) but not 20/20; 2X—10/20 (or 20/40) but not 15/20 (or

20/30); 3X—Cannot read at 10/20 (or 20/40). Defects other than inability to read the chart may be noted by either 1, 2X or 3X, according to degree.

(3) *Hearing*.—0—Normal; 1—Slight impairment in hearing, 15/20 but not 20/20; 2X—Evident impairment—10/20 but not 15/20; 3X—Marked impairment—cannot hear whispered voice at ten feet (10-20). If either ear is discharging pus the letter P is added.

(4) *Mouth Breathing*.—0—Normal; 1—Slight evidence of mouth breathing (may be temporary condition due to acute cold). 2X—Unmistakable evidence of mouth breathing which removal of adenoids would undoubtedly correct; 3X—Marked evidence of mouth breathing malocclusion; noticeable disfigurement. Adenoids undoubtedly responsible.

(5) *Tonsils*.—00—Tonsils have been removed, the base of the tonsil bed is smooth, shows no tonsil, and child knows that it has been removed; 0—Normal. Tonsil even with its surrounding cushion or distinctly behind it; 1—Slightly enlarged or protruding slightly from its surrounding bed; 2X—Tonsil large enough to reach half way across to the middle line of the mouth; 3X—Tonsil touching or almost touching its fellow on the opposite side.

Serial bulletins to all examiners and all departments covering the wide range of defects encountered are expected to remove discrepancies which have appeared in the records and to place the examinations made by different men on a comparable basis.

CASE RECORD FORMS

Keeping Up to Date

THE System of Hospital Case Record Forms devised by the American College of Surgeons has been in use in many hospitals for upwards of two years. From time to time new forms have been added as experience has shown the need. The College has issued a new bulletin covering these additions which has been mailed to all hospitals.

The Faithorn Company supplies these forms, well printed, on durable bond paper, at favorable rates. All new forms are added and revisions made as they are developed by the College. Rates on new forms are the same as given on other forms in our catalog.

Please note—We prepay all shipments, thus distance is no barrier to buying of us, and you receive the forms with no more inconvenience than if ordered locally.

Filing Devices

Next in importance to the keeping of accurate case records is an adequate system of filing. We supply loose-leaf binders for temporary filing, and filing cases with indexes for permanent file.

If you have not received our catalog and price list, we will be pleased to send upon request

DIPHTHERIA ANTITOXIN

Diphtheria Antitoxin *Plus Clarity*

Use a clear Antitoxin. Clarity of serum means less reaction. A cloudy product tends to aggravate the reaction from serum administration, especially in cases of older children and adults who require the larger doses.

Our antitoxins are free from sediment and contain a minimum of solids.

Supplied in reliable syringes containing the standard prophylactic and therapeutic doses of from 1,000 to 20,000 units.

Population Growth and Congenital Syphilis

The toll of congenital syphilis reaped in the form of an excessive stillbirth and miscarriage incidence, high infant mortality and large proportion of permanent disabilities among surviving children is universally experienced. Dr. S. Hata of Tokio, reports in the *International Journal of Public Health* that less than 10 per cent of the fetuses of syphilitic mothers will ultimately live a natural course of healthy life, and since only 60 per cent of the infected women under his care were apparently fecund, the number of surviving healthy children would at most be 10 per cent of 60, or 6 per cent. To nations whose populations have been devastated by the World War and whose problem of repopulation is paramount, such destructive loss from congenital syphilis is a matter of grave concern.

The experience of Dr. P. C. Jeans of St. Louis would indicate that about 10 per cent of all marriages involve a syphilitic individual, and agree with Hata's findings as regards the high incidence of infection in the offspring. The problem is further aggravated by the fact that there is an amazingly large number of women with a positive Wassermann but with no clinical manifestation of syphilis. Because of this common occurrence routine Wassermann examination of all pregnant women and immediate anti-syphilitic treatment of positive cases are recommended as the ideal method for preventing congenital syphilis. Such a practice would cast no more slur on the woman and her family than the procedure of applying silver nitrate to the eyes of all newborn babes. The discovery and treatment of syphilis in the pregnant mother signify fewer miscarriages and stillbirths, disease-free children, as well as healthful mothers.

"Filled Milk" Bill Favorably Reported

Shortly after the reconvening of Congress passage will be sought of the Voigt Bill prohibiting the shipment of filled milk in interstate and foreign commerce, the Committee on Agriculture having favorably reported on the measure. Charging that "filled milk" is an imitation of condensed or evaporated milk, which it exactly resembles in consistency, color, and taste, and that its cheaper production tends to displace pure milk products by the compound, the

bill specifically defines filled milk to mean any milk, cream, or skimmed milk to which has been added or which has been blended or compounded with any fat or oil other than milk fat. Penalties attaching to infringement of the proposed bill are applicable to principal, agents, or employees and the measure is sufficiently drastic to limit the manufacture and shipment of such products within the confines of the state in which it is manufactured.

It is not charged that the manufacturers either manufacture the compound or sell it in place of condensed or full milk, but in the opinion of the majority report, retailers have done so and a correct label is not sufficient to protect the public and, therefore, an industry which last year found a market for 200,000,000 pounds of skim milk which formerly had no market, must be put out of business.

The minority report sets out fully that the product is "not unwhole-

some, deleterious, or injurious to health, but a wholesome and nutritious food," that it is properly, clearly, and plainly labeled in compliance with existing laws, and that it offers opportunity to thousands of American people limited in finance to purchase this food at prices within reach when there is a world demand to reduce the price of necessities. The minority report goes on to say that there is no demand for this legislation except from those selfishly interested in removing competition, and that it cannot be held to restrict the use of dairy products.

Legislation against this industry, attempted in the states of Washington, New York, New Jersey, and Pennsylvania, failed of enactment. Carried to Congress, the outlook seems to favor enactment which would prevent the utilization of the vast quantities of skim milk which until the past few years were wasted or its food value used in uneconomical and unscientific ways.

Investigate Deficiency Disease

EXPERIMENTAL investigation of the deficiency diseases is of recent date, and no generally accepted plan of attack has been formulated. In order to obtain information as to the nature of the dietary deficiency producing a certain disease, a well defined method of procedure is necessary, such as to find a suitable experimental animal; to use a diet complete with respect to other food elements, but which produces the particular disease with regularity in the chosen animal; to find a food that prevents the disease when added to a given dietary proved inadequate and to find the minimum amount of this food necessary to confer protection. A further development would be to prepare extracts of this food that also confer protection. These rules seem quite simple, but many false conclusions have been drawn from experiments that ignored them. In the investigations conducted by Lieut. Col. Edward B. Wedder, Medical Corps, United States Army, reported in *The Military Surgeon*, August, 1921, the purpose was to learn as much as possible concerning the chemical constitution of the antiscorbutic substance. Only young healthy guinea pigs were used. On a suitable diet these animals developed scurvy with great regularity on about the fifteenth day, after which they lost weight rapidly and usually died

before the thirtieth day with all the lesions of the disease.

The following conclusions were drawn from the experiments: (1) Scurvy can be produced in guinea pigs with regularity by feeding a liberal and varied diet consisting of oats, mixed scratch feed, bread, sterilized milk, and hay. (2) Scurvy may be prevented by the daily addition of five grams of green grass or five c.c. of filtered orange, lemon, or grapefruit juice, and cured by larger amounts. (3) The antiscorbutic vitaliment is soluble in water, absolute alcohol, acetone, and commercial ethyl acetate. (4) The antiscorbutic vitaliment cannot be extracted from the partially dried juice by ether, chloroform, or carbon tetrachloride. (5) The antiscorbutic vitaliment differs from the beriberi preventing vitaliment in the following particulars: (a) The antineuritic vitaliment is absorbed by finely powdered animal charcoal. The antiscorbutic vitaliment is not so absorbed. (b) The antineuritic vitaliment is not so precipitated by phosphotungstic acid. The antiscorbutic vitaliment is not so precipitated, but is probably destroyed. (c) The anti-neuritic vitaliment is a nitrogenous base. The antiscorbutic vitaliment is apparently non-nitrogenous. (6) By means of solvents an extract has been prepared which is suitable for further chemical study.

Unguentine

An ideal surgical dressing for the treatment of burns, wounds, chronic ulcers and any abrasions of the skin or mucous membrane. It has an antiphlogistic, mildly astringent, antiseptic and stimulating action.

This is demonstrated by the almost immediate relief from pain when applied to an injury, the prevention of mild and restriction of acute infection, formation of healthy epithelial tissue from the edges of the wound, and the healing of chronic ulcers.

Sample and literature upon request.

Bryn Mawr to Hold Second Workers' School

By vote of the joint administrative committee of the Bryn Mawr Summer School for Women Workers in Industry, a second session of the school will be held next summer.

The first summer school held at Bryn Mawr from June 15 to August 15, had an enrollment of eighty-two students. Next summer the number of students will be increased to one hundred and a certain proportion of 1921 students will be allowed to return. The interpretation of the term "women workers in industry" to mean those who work with the tools of their trade in industry will be maintained. However, it has been decided to liberalize somewhat the requirements for the special group of students admitted on the basis of leadership in industry. This last group will, in 1922, as in 1921, be selected very carefully by a committee with Miss Mary Anderson as chairman.

In order to round out the work of the school from an educational point of view, a study of workers' education, in particular women workers' education, will be undertaken during the winter under the direction of Miss Ernestine Friedmann, the executive secretary of the Summer School, who will visit various centres of learning. Furthermore, it has been decided to obtain the help of an educational expert who in the summer of 1922 will study the methods of the school from an impartial point of view.

The scholarship plan of sending students to the school in 1921 will be retained in 1922. Mrs. Gifford Pinchot of Milford, Pa., will again be national finance chairman. She will be assisted by local finance committees in the districts from which the students will be recruited. It is planned to include in the membership of these committees active alumnae of Bryn Mawr, representatives of labor and women interested in the Bryn Mawr project.

Labor Union Insures Members

The International Brotherhood of Electrical Workers at their recent 16th annual convention provided for a life insurance for their members on the group insurance plan. This is one of the first of the labor unions to insure their members. The union conducts its own insurance, admits all members of one year standing without physical examination and graduates the amount of insurance up to \$1,000.

School Facilities Considered Inadequate

J. F. Abel, in a paper issued by the United States Bureau of Education, says that more than one-half million additional sittings must be furnished during the single year 1920-1921 if there is to be made provisions for all school children in the schools of fewer than one-third of the towns and cities of this country. During the first part of the present school year a questionnaire was sent to the superintendents of towns and city schools. Eight hundred and fifty-nine, or 66.2 per cent of the towns and cities, with a population of 2,500 and

over, report that they lack adequate school facilities, and add that they must have additional accommodations for 507,524 children, and estimate the cost of building at \$300,000,000. The need is not confined to any one section of the country, nor to any special class of cities. The figures, in proportion to adult population is greatest in the Middle Atlantic States, the states of the old Northwest Territory, second; and New England, third. The figures for the Middle West, South and West are lowest and approximately the same for the three sections. While housing seems to be inadequate in the large cities, there is a great need in the small cities.

New Haven Athletic Center

A MOVEMENT in which the famous athletes and coaches at Yale University are actively engaged has as its object the training of community leaders in athletic and recreational work so that New Haven's average citizen, the "man in the street," and the industrial worker may benefit at least indirectly from the work of these famous athletes. Dr. James Rowland Angell, the new president of Yale, has expressed himself as in hearty sympathy with the work.

David E. FitzGerald, Mayor of New Haven, is behind the movement also, with the Chamber of Commerce, the Board of Education, represented by Superintendent Frank Beebe, the New Haven Normal School of Gymnastics and other representative local bodies.

Two schools have been opened, one the School of Coaching and the other the School for Training Neighborhood District Recreation Leaders. Recreation covers athletics and play of all sorts. If recreational work of the right sort is to be done, leaders are required.

Thirty men have registered in the school for coaches and are giving their time voluntarily.

The School of Coaching conducted by New Haven Community Service, has for its Faculty Walter Camp, Charles Taft, Berny Tommers, Mosey King and "Izzy" Winters, and these distinguished instructors aim to convey the fundamentals of football, basketball, baseball and boxing to the student coach. Technic, theory, and practical demonstration combine to make the course interesting as well as instructive.

In the School for Training Neighborhood District Recreation Leaders,

Walter Camp deals with sportsmanship and the technic of coaching; Miss Katherine Cronin, Community Service recreation specialist, is lecturing on the subject of age periods and characteristics and suitable activities for each.

Dr. Anderson, the Director of Yale Gymnasium, will talk on the technic of leadership, the qualities of a good leader, and the handling of groups, etc. Organized play for indoor groups and for outdoor groups will be illustrated and there will be model meetings showing the methods of organizing groups for recreational and athletic activities.

Edward Embill, Secretary of Rockefeller Foundation; Dr. E. Hermann Arnold, Director of New Haven Normal School of Gymnastics; Henry J. Schnelle, Director of Recreation in Public Schools and Public Playgrounds; C. F. Northrop, Boy Scout Executive, and others will be active in the instructional work at the school. Sixty-eight members have registered as neighborhood recreational leaders.

The work of organizing various districts and neighborhoods is progressing, with working committees who will plan and carry through leisure-time activities in their own districts. Ten leagues have been formed embracing seven hundred boys, with sixty men cooperating, these comprising officials, managers and captains of teams.

The Board of Directors is a most representative one, including every shade of religious opinion and politics. Clergy of every denomination are on the board, a judge of the Supreme Court, bankers, professors and prominent labor men.

Lunchroom—Wilson and Co.

Make It Your "First Aid"

You recognize, of course, the great value of a warm, wholesome, nourishing noon lunch as a builder of reserve energy; why not do what thousands of other "guardians of health" are doing in industrial plants, schools and large retail establishments, making the lunchroom their "first aid" as a builder of loyalty, satisfaction and greater efficiency.

VITROLITE TABLE TOPS

are notable for their widespread use. There are reasons—they are the definition of whiteness itself, crystal smooth, with a flinty hard surface that defies all stains and food acids. They can be cleaned in a jiffy with a damp cloth. They save all table covers and the expense of laundering. They last a life time.

The American Dollar and "AMERICAN" Sterilizers

An advertisement worth the reading of any interested in the purchase of sterilizing equipment—and directed particularly to those seeking the most for their expenditure.

WITH all eyes centered upon Price, the purchasing power of the American dollar has never been so taxed as it is today.

We sense that you are not immune to the price appeal in the purchase of your equipment. You are seeking the very most your money will buy—and rightly so. It is, therefore, a source of keen satisfaction to us to know and be able to prove that

AMERICAN
A PRODUCT OF SPECIALISTS

Sterilizers and Disinfectors

at present prices represent the greatest Sterilizer and Disinfecter value obtainable. Notwithstanding the fact that they cost more to manufacture, due to the use of finer materials, more searching tests, more scientific and precise shop and machine work, more exacting inspection, and are consequently worth far more to the owner, they are sold today for less per unit of value than any similar apparatus made. Greater skill, greater specialization, greater achievement do not make the "AMERICAN" cost more—they do make it worth more.

And the purchase price, low as it is, is greatly lessened in the after years of uninterrupted service because of low maintenance and operating costs. Your dollar has been creditably spent when it goes for "AMERICAN" apparatus.

Descriptive bulletins, engineering data and specialists' counsel are free for the asking.

Behaviorists in Community Work

The behavioristic attitude is stated by William A. White, in the January issue of *Mental Hygiene*, to have been the direct means of identifying psychology as one of the biological sciences. In the study of normal psychology the objective approach is a necessity. The behavioristic attitude carries this observation method over to man. The method was distinctly warranted because the introspection of the older psychologists had become sterile when it came to having anything helpful to offer in the solution of man's vital problems of living. Mental reaction supplemented psychological adjustments, hence the failures of life came to be regarded as inability of the individuals concerned to meet the conditions imposed upon them by their environment, largely their social environment. Variations in conduct from social standards are merely more or less inadequate reactions of adjustment.

The whole matter is adequately summarized under twenty-five principles: (1) The organism is a complex of action patterns; (2) Man is what he *does*; (3) Perception, thinking, and feeding are but actions in process of adaptation; (5) The process of adaptation is the process of development and evolution; (6) All action implies tendencies and counter tendencies; (7) Therefore, what a man does he wishes to do; (8) The psyche is the head end of the organism and its history is the history of the relation of the organs; (9) The psyche is the final grouping of the action patterns integrated to serve the organism in its function as a unity; (10) The motives that lead to asocial and anti-social conduct are relatively undeveloped and infantile; (11) These motives lie in the unconscious; (12) Modern psychology places great emphasis upon the unconscious; (13) Society is an organism; (14) Maladjustment is always a psycho-social problem; (15) Its correction may be approached by trying to change either the individual or the environment, or both; (16) Changing the individual requires a knowledge of the internal evidence to elucidate the nature of his personal difficulties; (17) The internal evidence includes the evidence from the unconscious and the evidence from a clinical examination of the bodily organs; (18) Changing the environment is calculated to adjust it to the limits of the individual; (19) The environment includes social institutions that are far from perfect; (20)

Repression and elimination are only negative ways of procedure; (21) Punishment needs to be studied scientifically as a means for conditioning conduct; (22) A positive attitude of education and helpfulness is needed in addition; (23) The principle involved is that the individual and society are like machines composed of parts. The attempt should be made to bring the parts into more harmonious mechanistic adjustment to the end of a better

utilization of the energy; (24) The problem should be approached in a scientific frame of mind. Sentimentality is and sympathy may be dangerous, antipathic emotions are distorting, understanding and wisdom are essential; (25) These are the trouble men of the social corporation and should be looked to for the clear and disciplined thinking, that will be of aid in bringing about better conditions.

Baltimore Nutrition Study*

BY AN arrangement with the school board of Baltimore County, systematic medical examinations are made of the pupils of the public school by the Public Athletic League. If the examination fails to reveal any remedial defects, the child is awarded a "Health First" button, signifying that he is in perfect physical condition. In addition, a letter of commendation is sent to the child's parents, complimenting them for their care and interest regarding their child's health. If the physician does discover one or more remedial defects, but not of a nature to exclude him from participation in athletic activities, he is awarded a green button, which certifies the physician's permission to participate in general athletic activities. The parents are notified regarding these defects and urged to have them remedied. After

a brief interval, the visiting nurse visits the home of the child, to learn if the defect has been corrected, and if not, to help make arrangements to have this work done.

Incidentally, the examining physicians have undertaken a little research work in regard to nutrition, as indicated by height and weight in relation to age. In this connection, 4,372 children were weighed and measured, and the results tabulated, as per table shown. The height and weight tables published by the United States Government, prepared by Dr. Thomas D. Wood, were used throughout the study. As the summaries reveal, 20.08 per cent of the girls examined were 10 per cent or more underweight, while only 16.22 per cent of the boys were 10 per cent or more under weight for their height and age. The combined results show that 17.93 per cent of the children were under weight.

THE MILK PROBLEM IN SCHOOLS

It is important in serving milk to young and growing children and youths to give the proper percentage of butterfats in each and every glass served.

This cannot be done when milk is served by the old style dipper, pitcher or tank method. With such service some get the cream and others get the skim milk.

THE LYONS SANITARY MILK URN

is the accepted method of modern milk service. With this urn each and every glass of milk that is drawn contains the same and proper percentage of butter fat. This is accomplished by a simple but effective float tube which draws off exactly the right proportion of "top milk" for each glass, without mixing or agitating mechanism.

It makes no difference whether the milk remains in the urn 2 minutes or 24 hours. All you need to do is place the day's supply of milk into the urn and draw it out through the faucet as you need it.

The Lyon's Urn is easily cleaned, and thoroughly sanitary. The insulated walls maintain exactly the right temperature. The milk will always be sweet, clean, cold and fresh.

Another striking feature of the Lyons Urn is that the cover and faucet can be locked after each meal.

LYONS SANITARY URN CO.

235 East 44th Street New York City

The Lyons Sanitary Milk Urn is unexcelled for use in school and industrial cafeterias, diet kitchens, mess halls, Hospital Wards, Institutions, and for general service.

FAVORITE in the dining room

Chocolate Pie Made With GUMPERT'S CHOCOLATE PUDDING

AND no wonder! Gumpert's has such a delectable, satisfying taste, such a tempting, rich flavor, such an appetizing color and creamy consistency that it delights the most critical.

SAVING in the kitchen

A nine-inch pie can be filled with Gumpert's Pudding for only six cents. The ingredients—chocolate, cocoa, eggs, milk, starch, salt and flavoring—are in powdered form. Just add water, sugar; and boil. Pour into baked shells, and top with meringue.

Social Resources of the United States

A "Handbook of Social Resources of the United States" has just been published by the American Red Cross. It was prepared primarily for the use of the Red Cross workers and those in need of data on educational, health, nursing, social service, recreational, civic and community services for social improvement. Neither the temporary and local agencies are included, nor agencies doing work abroad, insurance, fraternal and other associations are included. It is in fact a coordination and correlation of the national agencies which are working together or apart as the case may be to develop and further their various schemes of construction and reconstruction. We note with surprise the omission of some of the health or medical organizations. The American College of Surgeons, while a professional group, has extensive plans which in their unfolding will affect vitally many of the issues of the future. However, some of the more technical associations are indexed and available through the publications of the American Medical Association.

A publication of this sort which states clearly and concisely the activities and purposes of the many different agencies should do much toward assisting the closer integration of existing social work and eliminate at least some of the unnecessary inquiry and duplication.

American Red Cross, Washington, 1921.

Mind and Work by Charles F. Myers

Present day application of psychology as affecting labor and as calculated to overcome individual unrest by the employment of rational methods to arouse the interest and initiative in the workman finds an excellent statement in "Mind and Work," by C. S. Myers. He gives the why and the how of movement study and fatigue analysis. The value and application of selection study, and the conscious and unconscious restriction of output by employer or employee are discussed.

Vocational psychology can only be advisory, not compulsory, save when it is applied to select the best applicants for a vacant job. It cannot successfully be imposed on workers without their cooperation. Hence workmen must come to desire it as a preliminary to the systematic instruc-

tion in the trades which must replace present haphazard opportunities for learning if they are to assume the dignity of a vocation.

To secure the changes necessary in present methods, the fundamental requirements of the men come first, and Myers considers the cooperation of the trade unions as essential, and as a further earnest of their efficient application he considers that an independent National Institute of Psychology and Physiology as applied to commerce and industry is essential. The book is quite the best summary of the subject we have seen.

G. P. Putnam's Sons, New York, 1921.

Functional Diagnosis

Functional diagnosis has become of late an important part of medical practice. The book on this subject by Max Kahn is therefore very timely. The present volume is complete, in a way too complete, in that it enters into minute details of tests long discarded. The authors show a profound knowledge of their subject and in most cases present the technique as well as the interpretation of tests in a simple, readable style. The book forms a valuable addition to medical literature.

W. F. Prior Company, Inc., New York, 1920.

Assessment of Physical Fitness

This book is an effort to reduce to mathematical formula the correlation of vital capacity—that is, the maximum amount of air exhaled in a single expiration following a maximum inspiration,—with certain other single physical measurements, such as (1) body weight, (2) length of trunk, (3) circumference of chest.

The author tabulates his series of measurements so that, his premises being accepted, the vital capacity in a given test may be quickly determined. A patient is rated as depressed in health if his vital capacity is 10 per cent less than that of his class and is considered as definitely abnormal when he registers 15 per cent below the average of his class.

The book is of vital interest to all who are concerned with physical education or race betterment, but if only for the simple reason that it makes no allowance for the personal equation, it cannot be considered final for arbitrary classification as to physical fitness.

Paul B. Hoeber, New York, 1921.

Year Book of Anesthesia and Analgesia

The science of anesthesia received the same stimulus and impetus to develop during the World War that the science of surgery and medicine received and, like them, did develop. The American Year Book of Anesthesia and Analgesia for 1917-1918, edited by Dr. F. H. McMechan, which has recently appeared, contains several articles which mark definite advances in their respective zones. The reviewer is pleased to note many articles which do not deal with purely clinical or empiric factors, but which have issued from the laboratory as well as from the anesthetizing and recovery rooms.

Surgery Publishing Co., 1921.

Transactions of American Child Hygiene Association

The transactions of the American Child Hygiene Association for the year 1920 have been published in pamphlet form and contain the addresses and discussions which took place at the St. Louis meeting. The presidential address sounds the need for membership, for cooperation, information and efficiency. One of the great accomplishments of the year, the formation of a council for Coordinating Child Health activities is spoken of. Mr. Hoover with his national and international ideas and contacts yet so "close to the great tragedies of child life in a great laboratory of mass action" develops a program for American children that the nation has an obligation and responsibility toward the children not based alone upon human aspirations but on the necessity to secure physical, mental and moral health for national, economic and social progress. The complexities, as he says, are not to be solved by governmental action alone, although it does much, but "When all public interest has expended itself, child development still rests with parents and parents need much waking up. Much can be done by waking the public conscience in every community. Much still remains to be carried out by action from the state in its local as well as national phases."

The problems of prenatal, maternal, and infant care, of the pre-school age, and adolescence as well as the vital and social statistics and health plays are all given detailed discussion.

Franklin Printing Company, Baltimore, 1921.

It Is Uniformly Pure

Throughout each process in the production of Carnation Milk, a uniform standard is always the prime consideration.

Carnation is just pure cows' milk evaporated to the consistency of cream. Only water is removed. Nothing is added, not even sugar.

Sealed in air-tight containers and sterilized, Carnation reaches you with all the natural food value retained.

Always pure, always wholesome, Carnation is widely used in every section of the country.

Write today for the Carnation book containing 100 recipes. It will be sent promptly on request.

HYGIENIC-MADE Individual Dressing Packets

*Most Convenient, Quickest, Simplest
Form of First Aid
Dressings*

Individual Dressing Packet designed to be carried as part of worker's regular equipment

The Only First Aid Kit Complying with Specifications of the Accident Prevention Committee of National Electric Light Association.

INDIVIDUAL Dressing Packets each contain one or more individual First Aid dressings specially prepared for a definite purpose. Each dressing is complete in itself, including compress and bandage, is sterilized and sealed in an envelope. Full directions are given on each packet by both picture and words, covering use of the contents. The dressings can be applied instantly by anyone. This is the most convenient, handiest, easiest to apply and least wasteful way to provide First Aid treatment for the protection of workers where the attention of physician or nurse is not immediately available.

Standardized Kits Containing Packets Covering Definite Classes of Hazards.

Assortment of I. D. P. selected to protect workers in all classes; isolated individuals or groups; inside, outside, male or female workers.

Specially Designed Kits to Meet Any Known First Aid Requirements.

The I. D. P. method can be applied to any First Aid requirement. We will design and equip Kits containing I. D. P. to cover the hazards of any industry.

Specifications and Costs on any I. D. P. equipment will be sent upon request, together with detailed information regarding this better method of furnishing First Aid Supplies and Treatment.

American Dietetic Association Meets

The fourth annual meeting of the American Dietetic Association, held in Chicago, October 24 to 27, 1921, presented in addition to the usual range of subjects on general dietetics and problems of administration a series of sociological studies which brought out the difficulties of dietaries which run counter to food prejudices, either racial or from habit. The clinical applications of dietetics occupied a section. The therapeutic phases of child feeding were especially illuminated by Dr. A. L. Daniels in her talk on "The Dietary Needs of a Children's Hospital." Fallacies in regard to food poisoning were uncovered by Dr. John Street, whose address gave highly practical suggestions with regard to food buying and food storing. The role of appetite with reference to nutrition was handled by Professor A. J. Carlson, of the University of Chicago, whose monumental research on the control of hunger in health and disease speaks for his authority on the subject.

The outlook on the whole subject is promising in view of the earnest

study of the subject as a specialty by nurses on whom ultimately the physician needs must depend for the intelligent handling of prescribed dietaries.

Congress of the American College of Surgeons

The recent Congress of the American College of Surgeons was notable for the spirited discussion of health versus new methods in medical and surgical treatment and in organization of medical service, as well as in the general trend of scientific research. Announcement was made at the meeting that a \$500,000 research academy as a monument to American surgery and as a tribute to the Late John B. Murphy, will be erected by the College on a site adjoining the Chicago home of the American College of Surgeons. The officers elected for the ensuing year were Drs. Harvey Cushing, Boston, president; Henry Sherk, Pasadena, Calif., first vice-president; and George P. Miller, Philadelphia, second vice-president. One new member of the board of regents was chosen and four re-elected: Daniel F. Jones, Boston, new member; George W. Crile;

Dr. John B. Deaver, newly appointed president of the American College of Surgeons.

Alexander Primrose, Toronto; Albert J. Ochsner, Chicago, and George E. de Schweinitz, Philadelphia. The next meeting will be held in Boston. Seven hundred and nineteen surgeons from all parts of the country were inducted into the College by the president.

AMERICAN COLLEGE OF PHYSICAL EDUCATION

Accredited—Co-educational

THE profession of Physical Director and Playground Supervisor is in the ascendancy. It makes possible the American ideal of "Efficiency through Fitness." One-half of the states require teaching of physical education. Therefore, Colleges, Universities, Public and Private Schools, as well as Summer Camps, Athletic Clubs, Industrial, Social and Community Centers, Banks, Manufacturing Plants, Department Stores, Y. M. and Y. W. C. A., are making constant demand for more trained men and women. The American College prepares and places through its free graduate placing bureau large numbers of these workers each year.

The American College offers two year, three year, and degree courses. We also offer a graduate placing bureau for the benefit of not only the graduates, but also for the employers of teachers of physical education. This service is rendered without cost to the student or the employer.

Clinical Laboratory Service For Physicians

The part that laboratory methods now play in the daily work of physicians is set forth in a recent editorial in the Journal of the American Medical Association, with a comment on the growth of laboratories of health departments and in hospitals to meet the constantly growing needs of physicians. The editorial rather deprecates the necessity that so large a proportion of this work must be entrusted to technicians and voices the demand that increasing facilities for this form of laboratory service shall be marked by no lowering of standards. The laboratory features of the proposed health centers or of institutions financed and controlled by the community promise an ideal service to the physician, but unless their organization methods and control are in fact actually in standards and practice controlled by the organized medical profession, the physicians are not properly discharging their responsibility to their patients. Any effort whereby clinical laboratories are multiplied to meet existing needs and are kept up to reasonable and fair standards is to be commended.

Dr. George Hoyt Whipple Goes to Rochester

George Hoyt Whipple, M.D., director of the Hooper Foundation for Medical Research at the University of California, and recognized as one of the leading pathologists in the country, has accepted the position of dean of the new College of Medicine, Dentistry and Surgery, now being organized in the University of Rochester (New York) on the nine-million-dollar foundation established by George Eastman and the General

Education Board, as agent of John D. Rockefeller.

Dr. Whipple was born at Ashland, N. H., on August 28, 1878, the son of Ashley and Frances Hoyt Cooper. He received a bachelor of arts degree at Yale in 1900 and was graduated from the Johns Hopkins University Medical School in 1905 and 1906 he was an assistant in pathology in the medical school of Johns Hopkins and for two years following that he acted as an instructor there under Dr. Welch.

In 1907 he went to Panama, where he was the pathologist of the Ancon Hospital, but he returned to Baltimore the next year to act in the same capacity in the Bay View Hospital. In 1909 he was made an associate in pathology at Johns Hopkins and was made an associate professor with Dr. Welch in 1911.

In 1914 he went to the University of California as a professor of research medicine. He also was appointed director of the Hooper Foundation of Medical Research, a branch of the medical school of the University of California maintained in memory of George William Hooper by his wife. He is a member of the American Society of Experimental Pathology, the Association of American Physicians, the American Physiology Society, the American Medical Association, International Association of Medical Museums, Sigma Xi, Alpha Omega Alpha, Phi Delta Kappa, Beta Theta Pi and a member of the Committee on Scientific Research of the California State Council of Defense.

Dr. Whipple has expressed himself as particularly interested in developing facilities for the care of part-paying municipal cases as an adjunct to the proposed medical school. Community service should be so utilized, however, as to contribute toward the turning out of the type of medical

practitioners, the sort who will through their investigative work develop both the means and the interest successfully to handle the larger phases of medicine and to contribute the large science of public health.

Goes to Bureau of Chemistry

Keystone View Co.

Dr. Wm. W. Skinner has been appointed assistant chief of the Bureau of Chemistry, Department of Agriculture.

Dr. Wm. W. Skinner has been given immediate charge of the scientific and research work of the Bureau of Chemistry, Department of Agriculture. This is one of the largest scientific organizations in the country, with between six and seven hundred employees. Dr. Skinner is a graduate of the University of Maryland and George Washington University and has pursued special studies in the University of Arizona and the University of California. He was for four years assistant chemist of the University of Arizona and has been associated with the Bureau of Chemistry for seventeen years.

The Control of Life

TO THE fear often expressed that scientific discovery, the development of machinery, and the world wide conditions of commerce and finance will concentrate wealth and power more and more in the hands of the few, J. Arthur Thomson in "The Control of Life" answers, that what we need is more science and that it is for lack of applied scientific knowledge we "muddle along, making all sorts of anachronistic and gratuitous mistakes."

It is obvious common sense to bring to bear on the problems of man's betterment the resources of the modern science of biology. While the present stage of our knowledge of Mendelian inheritance does not permit the predictability of types, genetic control is quite possible in certain innate or constitutional diseases, such as diabetes, epilepsy, feeble-mindedness, and glaucoma—which may be transmitted from generation to generation. So may determinative peculiarities of environment or nutrition, habits and occupation be detected and preventive measures, scientifically directed, look toward their control. An enlightened understanding of the limitations and dishar-

monies of man's constitution should enable individual standards of health which would insure a fair measure of resisting power to the invasion of disease-germs and other deteriorating influences, for, individually and collectively, we are called upon to pay our physiological bad debts. "Given an understanding of natural inheritance and the influence of nurture, given a pride of race and a pride in having a vigorous family, given an enthusiasm for health, many more positive methods of 'improving the breed' will occur."

Progress in evolution, of course, means a preponderance of strong fine types. Economic questions are involved with the growth of populations. The present tendency in all civilized countries toward declining birth rate is looked upon with alarm by eugenicists, but so far a relative balance has been maintained among peoples. A high birth rate is almost inevitably attended by a high death rate. Self-control and forethought in marriage and child bearing marks a superior people. Birth control is not "race suicide" but race-saving, according to Thomson. Mere carrying on is not progress. There must be increasing realization of fundamental

values. Obstacles and hindrances to the development of higher types that will be staple and persistent will be overcome only by a fuller realization of the physical and biological preconditions which secure those types.

This book by Thomson is a distinctly worth while consideration of the broader aspects of the correlated facts of science and their application to practical problems.

Henry Holt & Co., New York, 1921.

Austrian Women Combine on Health Work

The important women's organizations of Austria have combined to form the Women's Anti-Tuberculosis Society of the Red Cross of German Austria, in order to check tuberculosis, which is especially prevalent among the growing generation. The objects of the society are to obtain money for carrying on the work, train women for service in connection with sanatoria, and do educational work.

We live in an age of more or less constructive criticism, based upon the beginning at least of scientific research.—Todd.

Life Training is Planned for Orphans

From cradle to workshop the American Argonne Association, under the supervision of Dr. Royal Stross Haynes of Columbia University, is taking two hundred French war orphans. The aim of the Association, as reported in the *Chicago News*, is to bring the best fruit of American science and sociology as a contribution to the orphan problem in France, demonstrating how to give the children more personal continuous care and education than is now possible for the same amount of money.

The Association was founded soon after the armistice by Dr. Haynes, who, then associated with the Red Cross, has now perfected an institution that is sustaining and educating its charges at the actual cost of about one hundred and fifty dollars annually in American money, including all expenses except the capital investment.

The peculiar feature of this institution especially interesting to sociologists is the fact that the children are under continuous direction from infancy until they leave to take a job. In all other dependent children's in-

stitutions the children are obliged to jump from institution to institution, and hence there is no continuity or plan in their education.

Dr. Haynes has endeavored to try this experiment in the United States, but was unable to do so because it would require a rearrangement of existing institutions. However, France, with nearly one million war orphans, demanded new workers and new methods.

Surgeon General Orders Clinic at Army Hospitals

Surgeon General Merritte W. Ireland has given instructions that wherever material is available a clinic be held once a week in army hospitals and attended by all medical officers. All interesting cases are to be presented, examined and discussed. Demonstrations are also to be given in operating-room technic, new procedures in laboratory methods, and in roentgen-ray laboratories. In all those cases terminating in death the officers are to be assembled for discussion of the pathologic report and the clinical findings. Conferences frequently on sanitation and communicable diseases are ordered in all the army hospitals.

Medicolegal Decision in Communicable Disease

A recent Alabama case came up under the Legislative Act of 1919, page 936, Section 17, Subdivision 15, Adm. Act October 12, 1903, which authorized the isolation of persons having communicable diseases in hospitals, and the Act of 1919, p. 936, Sec. 17, Subd. 16, which authorizes the establishment of a hospital for the isolation of persons having a contagious disease. The Court held that persons having a contagious disease can only be quarantined in a hospital and cannot be confined in a jail. Especially is this true where they have given bond their appearance to answer the criminal charge which has been made against them. It is added that in order to prevent the spread of contagious and infection, the legislature can, under its police power, establish quarantine and authorize governmental agencies to enforce all reasonable ordinances necessary to attain the desired results, including the segregation or isolation from the public, either in their homes or hospitals, or camps prepared for that purpose, of persons afflicted with contagious or infectious diseases.

It's Good Business

*Preventing human beings from suffering,
injury and death is humanitarian, but
it is also the best kind of good business*

THE Safety Section of the United States Railroad Administration reports for 1919 an actual saving of \$4,000,000.00 through accident reduction by safety work; and the United States Shipbuilding Board, a saving of \$10,800,000.00 for the same period! Of course, these are gigantic enterprises, but the results also are gigantic, and, after all, were accomplished by the individual efforts of hundreds of member plants of these industries.

Your plant is a member plant of your industry. Are your savings through Accident Prevention as large as they should be? Would a 75% reduction of your accidents interest you?

The National Safety Council can help you to effect this 75% reduction. It offers to you all the accumulated accident prevention experience of America, and the only organized accident prevention service in existence which has demonstrated that it cannot fail to help you.

A letter to our Business Division will bring full details of membership and service.

Fair Questions

Is there a better or safer antiseptic, or germicide, for all-round surgical, medical or hygienic use than

peroxide of hydrogen?

Is there a purer, more stable or better peroxide of hydrogen than

Dioxogen?

Is there any antiseptic more widely or generally employed in clinics, hospitals, offices, factories, schools and homes by physicians themselves, or on their recommendation, than

Dioxogen?

Need more be said?

**THE
OAKLAND
CHEMICAL
CO.**

**59 Fourth Ave.
New York City**

In purity and oxygen-liberating power, Dioxogen exceeds U. S. Phar. standards for H_2O_2 by 25%.

Dioxogen is odorless, almost tasteless, and entirely free from acids and acetanilid. It is also colorless and does not stain the skin.

Absolutely non-poisonous and non-irritating, Dioxogen is not only the most potent, but the safest and most harmless of antiseptics.

Applied to wounds, Dioxogen promptly destroys bacteria and stimulates the reparative processes of the tissues.

Dioxogen is the one powerful germicide at the physician's command that can be freely used anywhere and anytime without the slightest danger.
